Negatives, Intensifying	692	Cooper Hewitt Mercury Vapour Lamps	123, 124, 125, 126, 127, 128, 129, 130, 131, 132, 133, 134, 135, 136, 137, 138, 139, 140, 141, 142, 143, 144, 145, 146, 147, 148, 149, 150, 151, 152, 153, 154, 155, 156, 157, 158, 159, 160, 161, 162, 163, 164, 165, 166, 167, 168, 169, 170, 171, 172, 173, 174, 175, 176, 177, 178, 179, 180, 181, 182, 183, 184, 185, 186, 187, 188, 189, 190, 191, 192, 193, 194, 195, 196, 197, 198, 199, 200, 201, 202, 203, 204, 205, 206, 207, 208, 209, 210, 211, 212, 213, 214, 215, 216, 217, 218, 219, 220, 221, 222, 223, 224, 225, 226, 227, 228, 229, 230, 231, 232, 233, 234, 235, 236, 237, 238, 239, 240, 241, 242, 243, 244, 245, 246, 247, 248, 249, 250, 251, 252, 253, 254, 255, 256, 257, 258, 259, 260, 261, 262, 263, 264, 265, 266, 267, 268, 269, 270, 271, 272, 273, 274, 275, 276, 277, 278, 279, 280, 281, 282, 283, 284, 285, 286, 287, 288, 289, 290, 291, 292, 293, 294, 295, 296, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310, 311, 312, 313, 314, 315, 316, 317, 318, 319, 320, 321, 322, 323, 324, 325, 326, 327, 328, 329, 330, 331, 332, 333, 334, 335, 336, 337, 338, 339, 340, 341, 342, 343, 344, 345, 346, 347, 348, 349, 350, 351, 352, 353, 354, 355, 356, 357, 358, 359, 360, 361, 362, 363, 364, 365, 366, 367, 368, 369, 370, 371, 372, 373, 374, 375, 376, 377, 378, 379, 380, 381, 382, 383, 384, 385, 386, 387, 388, 389, 390, 391, 392, 393, 394, 395, 396, 397, 398, 399, 400, 401, 402, 403, 404, 405, 406, 407, 408, 409, 410, 411, 412, 413, 414, 415, 416, 417, 418, 419, 420, 421, 422, 423, 424, 425, 426, 427, 428, 429, 430, 431, 432, 433, 434, 435, 436, 437, 438, 439, 440, 441, 442, 443, 444, 445, 446, 447, 448, 449, 450, 451, 452, 453, 454, 455, 456, 457, 458, 459, 460, 461, 462, 463, 464, 465, 466, 467, 468, 469, 470, 471, 472, 473, 474, 475, 476, 477, 478, 479, 480, 481, 482, 483, 484, 485, 486, 487, 488, 489, 490, 491, 492, 493, 494, 495, 496, 497, 498, 499, 500, 501, 502, 503, 504, 505, 506, 507, 508, 509, 510, 511, 512, 513, 514, 515, 516, 517, 518, 519, 520, 521, 522, 523, 524, 525, 526, 527, 528, 529, 530, 531, 532, 533, 534, 535, 536, 537, 538, 539, 540, 541, 542, 543, 544, 545, 546, 547, 548, 549, 550, 551, 552, 553, 554, 555, 556, 557, 558, 559, 560, 561, 562, 563, 564, 565, 566, 567, 568, 569, 570, 571, 572, 573, 574, 575, 576, 577, 578, 579, 580, 581, 582, 583, 584, 585, 586, 587, 588, 589, 590, 591, 592, 593, 594, 595, 596, 597, 598, 599, 600, 601, 602, 603, 604, 605, 606, 607, 608, 609, 610, 611, 612, 613, 614, 615, 616, 617, 618, 619, 620, 621, 622, 623, 624, 625, 626, 627, 628, 629, 630, 631, 632, 633, 634, 635, 636, 637, 638, 639, 640, 641, 642, 643, 644, 645, 646, 647, 648, 649, 650, 651, 652, 653, 654, 655, 656, 657, 658, 659, 660, 661, 662, 663, 664, 665, 666, 667, 668, 669, 670, 671, 672, 673, 674, 675, 676, 677, 678, 679, 680, 681, 682, 683, 684, 685, 686, 687, 688, 689, 690, 691, 692, 693, 694, 695, 696, 697, 698, 699, 700, 701, 702, 703, 704, 705, 706, 707, 708, 709, 710, 711, 712, 713, 714, 715, 716, 717, 718, 719, 720, 721, 722, 723, 724, 725, 726, 727, 728, 729, 730, 731, 732, 733, 734, 735, 736, 737, 738, 739, 740, 741, 742, 743, 744, 745, 746, 747, 748, 749, 750, 751, 752, 753, 754, 755, 756, 757, 758, 759, 760, 761, 762, 763, 764, 765, 766, 767, 768, 769, 770, 771, 772, 773, 774, 775, 776, 777, 778, 779, 780, 781, 782, 783, 784, 785, 786, 787, 788, 789, 790, 791, 792, 793, 794, 795, 796, 797, 798, 799, 800, 801, 802, 803, 804, 805, 806, 807, 808, 809, 810, 811, 812, 813, 814, 815, 816, 817, 818, 819, 820, 821, 822, 823, 824, 825, 826, 827, 828, 829, 830, 831, 832, 833, 834, 835, 836, 837, 838, 839, 840, 841, 842, 843, 844, 845, 846, 847, 848, 849, 850, 851, 852, 853, 854, 855, 856, 857, 858, 859, 860, 861, 862, 863, 864, 865, 866, 867, 868, 869, 870, 871, 872, 873, 874, 875, 876, 877, 878, 879, 880, 881, 882, 883, 884, 885, 886, 887, 888, 889, 890, 891, 892, 893, 894, 895, 896, 897, 898, 899, 900, 901, 902, 903, 904, 905, 906, 907, 908, 909, 910, 911, 912, 913, 914, 915, 916, 917, 918, 919, 920, 921, 922, 923, 924, 925, 926, 927, 928, 929, 930, 931, 932, 933, 934, 935, 936, 937, 938, 939, 940, 941, 942, 943, 944, 945, 946, 947, 948, 949, 950, 951, 952, 953, 954, 955, 956, 957, 958, 959, 960, 961, 962, 963, 964, 965, 966, 967, 968, 969, 970, 971, 972, 973, 974, 975, 976, 977, 978, 979, 980, 981, 982, 983, 984, 985, 986, 987, 988, 989, 990, 991, 992, 993, 994, 995, 996, 997, 998, 999, 1000		
Collotype, Invention (Hist.)	867	Action	162	"Eastman" Plates (Rev.)	456
Mercurous Oxalate	333	American	161, 295, 1018, 1039	Eclipse, The Solar	662, 701
Negatives, Intensifying	692	Bill, A Proposed	1066	Photographing the. By J. I. Pigg	705
Plates, Moistening (Pat.)	674	Claim for \$250,000	747, 749	Eder's Jahrbuch (Rev.)	793
Troubles, Two	171	Foreign	143	"Recepte" (Rev.)	817
Varnish (Ans.)	279	Law, Points in	404	Edinburgh Photographic Club and the Scottish Federation (Cor.)	273, 397
without a Press	587	in a Painting	265	Edinol, Staud Development with	39
Colour Filters, Selective. By F. Monpillard	587	in Cinematograph Films	961, 998, 1002	Edwards, B. J., & Co.	899
Colour Photography Apparatus	375, 454, 589, 694	in France	438, 441, 581, 618	Elofsten's Half-Tone Screen (Hist.)	125
Brasserie's process on paper	1021	in Germany (Hist.)	4	Employers and Assistants	623
(Pat.)	694	in Groups (Ans.)	40	Emulsion, Lissac's (Pat.)	937, 938
Colour Photography Demonstration. By Sir W. Abney (Soc.)	975	in Portraits	561	Inventions (Cor.)	937, 938
Electrolytic	964	in Proofs Unpaid for	489, 499, 519, 522, 538, 581	Rapid Chloride	525
Filters. By Dr. Kömte	964	in South Africa	321	Washed (Hist.)	525
Gradation in	367	in the Transvaal (Cor.)	78	Work, Big (Hist.)	249
Lippmann	505, 964	International	404	Written Precipitation Process (Hist.)	37
"Stars Star" Process	815, 1030	of a Photograph	36	Fine Grained	1008
Miethe's, in London	268, 302, 311	Some Aspects of Photographic	683	in 1840, Herschel's Aim at (Hist.)	128
Multiple Tissue (Pat.)	73	Union, The	483, 548	Microscopy of	943
with Pigment Films. By H. O. Klein	768	Corros. Impregnation in	727	Elberfeld Paper Factory Co.	143
Colour Photography Pinatype Process	182, 722, 816, 749	Corona, Photographing the	506	Electrical Transmission of Photographs	525, 544
Plates, Filters and Inks for	13	Crayon, Fixatif for	268	Eikonogen-hydroquinone Developer	947
By Arthur Fayre	13	Criminals Caught by the Camera	506	Electron Photography	963
Povrie-Warner Process	1029	Photography and	191	Eikonogen-hydroquinone Developer	947
Principles. By A. J. Bull	447, 467	Crimson Tones on P.O.P.	279	Election Photographic	963
Schinzel's One Plate Process	608	Crooke-Irving Case	551, 577, 907	Elofsten's Half-Tone Screen (Hist.)	125
(Pat.)	608	Crystals (Soc.)	736	Employers and Assistants	623
Sensitized Plates for (Pat.)	90, 92	Curved Metal Plates, Printing on	48	Emulsion, Lissac's (Pat.)	937, 938
Smith's Multi-film	194, 356, 722	Cyanide by Dealers, Sale of	962	Inventions (Cor.)	937, 938
"Solgram" Process	902	Fixing with (Hist.)	309	Rapid Chloride	525
Transparencies	375, 466	Lantern Slides with Aniline Dyes. By W. Baskshaw	134	Washed (Hist.)	525
Trichromes on Paper (Soc.)	947	Cyanine Dyes, The Chemical Inwardness of the	145	Work, Big (Hist.)	249
Triple Plate Holder for (Pat.)	10	Sensitizers, The New...	828	Written Precipitation Process (Hist.)	37
Values of Daylight in	226	DAGUERRE and French Government (Hist.)	445	Emulsions, Ammonia in (Cor.)	37
Without Filters (Pat.)	111	and Niepce (Hist.)	324, 967	Fine Grained	1008
Zander Process	1023	Death of (Hist.)	526	in 1840, Herschel's Aim at (Hist.)	128
Colour-printing from Aluminium	190	Memorial to (Hist.)	864	Microscopy of	943
Colour Screen Holder (Pat.)	694	Daguerre's Diorama (Hist.)	163, 509, 526	Elberfeld Paper Factory Co.	143
Combination of Glass by Natural Solar and other Radiations. By Wm. Crookes	280	English Patent (Hist.)	624	Electrical Transmission of Photographs	525, 544
Coloured Lenses	242	Researches (Hist.)	657	Eikonogen-hydroquinone Developer	947
Colouring Albumen Prints (Ans.)	39	Daguerreotype, Cost of Working the	42	Electron Photography	963
Prints	509, 549, 609	in Embryo (Hist.)	66	Elofsten's Half-Tone Screen (Hist.)	125
for Three-Colour Half-Tone	411	in 1836 (Hist.)	388	Employers and Assistants	623
Lantern Slides with Aniline Dyes. By W. Baskshaw	134	Pictures Copying	942	Emulsion, Lissac's (Pat.)	937, 938
Colours, Spectroscopic Photography in (Soc.)	181	Publication of (Hist.)	47	Inventions (Cor.)	937, 938
Portraits in (Cor.)	678	Daguerrestype, Restoration of	868	Rapid Chloride	525
Combination Printing (Soc.)	394, 893	(Cor.)	878, 897, 901, 936	Washed (Hist.)	525
Masks for (Pat.)	933	Bromizing (Hist.)	962	Work, Big (Hist.)	249
Combining Several Figures in One Negative. By Harold Baker	814	Dark Room, Warming the	823	Written Precipitation Process (Hist.)	37
Companion, The Dark-Room (Rev.)	778	Illustration (Soc.)	515	Emulsions, Ammonia in (Cor.)	37
COMPANIES REGISTERED:—		Portable (Pat.)	515	Fine Grained	1008

EX CATHEDRA.

Anniversaries. The series of notes on the history of photography which commence on another page disguise by their arrangement a fact which should aid the systematic student of past methods in photography, and that is, the connecting thread which runs all through the processes from first to last. Almost every worker has based his new process on that of his predecessors, often without a proper appreciation of the conditions under which that process was worked. This fact can be discovered in almost every advance, great and small, and it has the classical precedent of Fox Talbot, who borrowed the idea of development from Daguerre, and possibly also, as there is evidence to show, from the Rev. J. B. Reade.

Reviews of the Year.

Photography is classed with other chemical arts in the two leading German summaries of chemical progress. The "Technisch-Chemisches Jahrbuch" holds fairly closely to patents and scientific notes, and neither it nor Dr. Richard Meyer's "Jahrbuch der Chemie" attempts to review the whole literature of photography and photo-chemistry. Indeed, exigencies of space—their whole field is a very large one—prevent them from treating the subject in the detail which photographers would wish to see it done. Drs. Eder and Valenta, who are the abstractors for the second of the yearbooks, are extremely catholic in their citations of authorities, and we find them recording the general statement that properly stored dry-plates will keep in good condition for a long time—according to "W. D. Welfars." And on the next page they proceed to give an uncalled-for lightness to the present Treasurer of the Royal Photo-

graphic Society by crediting a paper of his to "J. Sherry." They ought to get their proofs corrected in England.

A Public Photographic Library.

The Patent Office Library, which has newly catalogued its photographic books, is the place where many a technical journalist is accustomed to verify his references. "Laissez faire" is the unwritten motto of its management, and probably no other library, English or foreign, offers equal facilities for research in the literature of technology. The Royal Photographic Society possesses a more complete collection of photographic books and periodicals, but, though it extends its courtesies to accredited students, it is not available to the public as is the Patent Office. In Southampton Buildings the signing of your name gives you the entrée to a library which must surely stand alone in the freedom granted to the readers in consulting the contents of the shelves. It is reported that photographic authors have been seen there extracting unwritten testimonials to their works from the dirtiness of their pages, and viewing, as a proof of popularity, the well-thumbed volume which bears their name.

More Cinematograph Accidents.

In another column we chronicled two more cinematograph accidents that occurred last week. It is noteworthy that at the large London houses where the cinematograph is in nightly use an accident very rarely, if ever, happens—the operators being all careful and experienced hands. In most instances nowadays when an accident occurs it is at a children's entertainment and at the hands of amateur lanternists or inexperienced operators, who do not fully realise the highly inflammable nature of the films they are dealing with. Lanterns and films are now to be had on hire, and very frequently the hirers are quite unaware of the combustible character of the films, and treat them very much the same as they would ordinary glass lantern slides, with the result that we sometimes hear of a scare amongst the audience, if nothing worse, and the operator suffering from burns. If the film be allowed to rest in the lantern, unless the light be previously shut off, a "blaze up" must be expected. A non-combustible film, as thin and flexible as celluloid, is still a desideratum, and a small fortune awaits the inventor of one. Various patents have, from time to time, been taken out for denitrating nitro-celulose, but they have turned out of no practical value so far as cinematograph films are concerned.

Photographic Fashion Plates.

Can the camera compete with the human draughtsman in the production of the ever-changing shapes which the eternal feminine assumes at the dictates of fashion? A writer in

the "Strand Magazine" takes a semi-hopeful view. But the photograph must show the fashion-plate woman as seven feet high, and with a ten-inch waist, if it is to compete with the creations of the artist. Large sums are paid to fashion-plate artists, and it is one of the branches of modern illustration which has attracted a large number of clever workers, whose "creations" are the weekly study of fashionable and would-be fashionable womankind. "Photography (says the "Strand") will never quite replace these, because the best photograph, charming as it is, still allows little folds and creases which mar the general effect. In photography you can idealise only up to a certain point. You can embellish, but you can't produce a line, or a fold, or a curve that is not there. If the photographer had the skill and knowledge of dress to pose his sitter to perfection. I've often thought that if such an atelier were established in London, I should like a hand in it. In fact, I can't help thinking photography on these lines will produce the fashion-plate of the future." This lay view under-rates the powers of the retoucher in photography, and, indeed, the optician, if it was worth his while, might provide for the alteration of the lady's figure to give it the present vogue. But according to one confession, the most faultlessly-dressed model never looks like a fashion-plate in the photograph, nor does any dress hang like a fashion-plate dress. "A photograph always makes a woman look dumpy, and dumpiness is out of fashion."

Explosive Flash Light Compositions.

One day last week some of the half-penny papers created a little sensation by announcing on their placards a mysterious explosion at the General Post Office, etc. The real facts appear to be these. A sorter in the Mount Pleasant depot, at one of the tables, came across a cardboard box bearing a penny stamp, and marked "Fragile," and tossed it lightly into a basket of correspondence going in the same direction, when it exploded, and a blue flame shot up, brightly illuminating the place. The flame was quickly put out, and no damage was done beyond that some of the letters in the basket were slightly scorched. The packet which had exploded, it is stated, was blown to atoms, but there was sufficient left in the fragments to enable the officials to trace the sender, who is a London photographic dealer. It appears that the packet contained a flash light composition which was sent to the order of a country customer. Now it is illegal to send any explosive through the post, and the sender is liable to prosecution. The explanation given by the dealer—that he had no idea that the substance would be exploded by a slight concussion—was considered by the postal authorities, and a prosecution will not be instituted. Many of the flash light compositions are highly dangerous unless they are handled with the greatest care, and this we have many times pointed out to our readers. Whenever we have been asked for formulæ for flash light powder we have always endeavoured to impress on the applicant the danger that may be incurred in compounding them, and advised the use of magnesium or aluminium powders by themselves, with one of other of the lamps now on the market. When this method of using the flash light is adopted there is no danger whatever to the operator, provided he stands clear of the flame, which usually extends to a considerable distance, particularly when a large quantity of the powder is employed.

The Nottingham Camera Club.—Sir Henry Cotton, K.C.S.I., has promised to open the photographic exhibition that is being arranged by the Nottingham Camera Club for early in April next.

UNCORRECTED LENSES.

THE article which we publish elsewhere on "Artistic Lenses," by Major Puyo, is interesting as letting a little light on to part of his method of obtaining those results which have been so much admired here.

The use of uncorrected lenses for obtaining softness of definition is no new idea. At the Camera Club Conference in 1893, Mr. Rowland Briant showed some extraordinary results obtained by the use of spherocylindrical lenses, though these were used in conjunction with slit diaphragms, which were placed parallel to or at varying angles with the axis of the cylinder. A year or two later a special set of uncorrected spectacle lenses, all fitting into one mount, were placed on the market by Dollond and Co., and these were plano-convex, or crossed lenses, ranging in focus from eight to twenty-four inches with an actual diameter of nearly two inches. One of these sets which came into our possession, we used with excellent results, and with varying effect, for although a table was issued showing the necessary correction for the actinic focus, yet varying degrees of softness of definition could be obtained by more or less disregard of the correction, and placing the plate practically at the visual focus.

In the exhibition of the R.P.S. in 1895 were some portraits by Mr. J. S. Bergheim which attracted a good deal of attention at the time, because of the very delicate softness of definition which just stopped short of actual fuzziness. These were produced by the Dallmeyer-Bergheim lens, which is practically a simple portrait lens, the front being an uncorrected positive meniscus and the back a single lens of negative focus, the distances between being variable, thus giving considerable latitude of focal length and what might be called great depth of focus. The full working aperture of this lens was practically $f\ 9$, and the spherical and chromatic observations were purposely uncorrected in any way, for Mr. Bergheim claimed that better results, that is to say, more painter-like effects were obtained by the use of this lens with its outstanding corrections than with a lens which was more perfectly corrected. This lens was free from distortion, and practically covered the plate with uniform definition or want of critical definition from edge to edge.

There is one point in Major Puyo's article about which we are not quite clear. He states that he uses lenses of from 80 to 100 c.m. focus, some of which work at an aperture of $f\ 5$, and that the cost of them is trifling. This means nothing more nor less than crown glass discs of from six to eight inches in diameter. These cannot, if optically worked at all, be of trifling cost, and unless he uses merely the half of a condenser made of St. Gobain plate, and one might almost imagine that he does, as he states that his lenses are plano-convex, one must wait for further information before accepting this in toto.

The use of uncorrected lenses of small aperture is by no means new, of course. Steinheil in 1865 introduced his periscopic lenses, which were composed of two crown meniscuses placed rather close together with a very small stop, $f\ 40$, placed midway. In the following year Zentmayer, of Philadelphia, U.S.A., improved on this by making the back lens of shorter focus, and placing the diaphragm nearer the back lens. Both these lenses were, however, wide-angle lenses, and embraced a fairly wide angle. For many years Rodenstock, of Munich, has placed on the market both landscape and doublet objectives, composed of uncorrected lenses and the Rathenower Optische Anstalt have a convenient casket set of such lenses.

Many of the lenses used in the cheaper form of hand cameras, particularly of Continental manufacture, and of the box type, are fitted with periscopic lenses, and with these the correction for the actinic focus is made once and

for all; but in every case they work at comparatively small apertures.

The use of uncorrected lenses of large aperture, particularly of the meniscus form, is quite permissible for those who wish to obtain softness of definition for the outstanding spherical and chromatic aberrations prevent anything like critical definition being obtained, and give that peculiar effect which is called "painter-like" by the pictorial photographer. That these lenses also possess so-called great depth of focus is another feature in their favour from the same point of view, and this is due to the fact that there being no plane of critical definition, the plate may be placed within a fairly wide range both before and behind the visual focus without much difference being seen. Personally, we believe that equally satisfactory results may be obtained by the judicious use of a corrected lens, and whilst the latter may be used for artistic work, and is at the same time always ready to give critical definition when so required to do, whereas the uncorrected lens will not help us in the latter case, it seems the more reasonable to choose the most perfect tool we can get rather than a makeshift.

PHOTOGRAPHIC LITERATURE.

THE re-issue of the list of photographic books and periodicals in the library of the Patent Office seems the occasion to draw attention to the collection brought together there primarily for the purposes of patentees and disputants of patents, but open to the public every week day from ten to ten. We are probably right in describing the collection as more completely representative of photographic literature than any other provided in the public interest. It may be that the British Museum is better off, but in the absence of a class list a comparison is practically impossible. Moreover, the labour of consulting any great number of works at the British Museum library would deter any one from devoting days there to a search which could be made in hours at the Patent Office. The new catalogue thus represents the most perfect means, at the disposal of British photographers of making any research into the history of the craft, of ascertaining the validity or invalidity of a patent or the anticipation of an invention. If conclusions can be drawn from articles and processes which are patented at the present time, there must be many inventors to whom the Patent Office library is a "terra incognita," and for this reason among others the widest publicity should be given to the opportunities granted under the Patent Laws. The system of granting protection by Royal Letters Patent to nearly anything, at the same time providing the means of proving the invalidity or otherwise of the patent, may not be a perfect one, but the Patent Office carries out the latter part of its contract with commendable efficiency. With the aid of the lists such as the one just issued the inventor or investigator is given every chance of acquainting himself with the results of workers in the same sphere as that in which he has been labouring, and that is an opportunity which may be impressed upon every one, occupied with original work in photography, who is within easy access of the library.

The arrangement of the present list* is one which will probably give the photographer a good deal of annoyance before he discovers his way about it. As explained in a preface, it consists of two parts. The first, which occupies nine-tenths of the volume, is an alphabetical list of subject-headings, with entries, in chronological order,

belonging to each. The second part consists of a series of keys, or summaries, of these headings in class order, that is, apparently on the plan according to which patent specifications are classified.

As the list includes works on printing and other graphic arts besides photography, all the references in the earlier and later parts of the list are brought together under P within the space of fifty pages. In the arrangement of these pages, the chief alphabetical headings are:—Photochemistry, Photo-enamels, Photographic, and Photography, and it is the sub-headings which describe or indicate the character of each section. Under this scheme printing processes is included under "Photographic," but "Development and Developers" fall under "Photography" thirty pages later. Doubtless there are good bibliographical reasons for this, but the arrangement seems to us puzzling, and the best thing the student can do is to begin with the key in Part II., which will direct him to the subject he is seeking.

In other instances the bibliographical instinct appears to have got the upper hand of the compiler, who might have sacrificed classification of the works as books to arrangement of them as bearing on photography. Because certain works on photographic chemistry are written under an alphabetical scheme, they go under "Dictionaries" on page 219, whereas, photographically speaking, they are more fitly placed under "Photographic Chemistry" on page 205. True, there is a reference under this latter heading to "Dictionaries," but the bibliographer has his way.

We mention these facts to show that it will be to the advantage of any one paying a visit to the library to familiarise himself with the ins and outs of the list beforehand. The compilers, too, who are now engaged on the long-expected list of the Royal Photographic Society's library are also urged to moderate any bias they may have towards conventions of the bibliographer. A scheme of subject classification which is based, say, on the natural history of a photograph from emulsion making to the finished and mounted print, will probably be more readily followed than an arbitrary arrangement which is without such obvious frame-work.

But we would not appear to underrate the labours of the Patent Office librarians, for the list bears many evidences of the care with which they have sought to provide a reference to their literature whenever the searcher would be aided thereby. To take an example, they include "The Art of Retouching," by J. Hubert, under "Portrait Photography," as well as under "Photographic Retouching," because it contains chapters on portraiture by day and flash light. And so in other cases they are at pains to bring out the miscellaneous contents of many of the older text-books.

Though they follow convention in contracting Christian names into initials, whereby one well-known writer becomes scarcely recognisable as "C. Jones," they are equally strict in printing in full such titles as the following of a work issued in 1840:—

"Electro-magneto-tipia ossia spiegazione teorico-practica di come succedano le naturali impronte degli oggettivi chiamanti Daguerreotype."

And they even mildly correct the vulgarity of a writer on "P.O.P." by turning it into "P(rinting) O(ut) P(aper)."

H.M. CONSUL at Boston, U.S.A. (Mr. W. Wyndham) reports that inquiries have been received at his Consulate for the names of manufacturers of magic lantern slides on agricultural subjects. Communications should be addressed to H.B.M. Consul, British Consulate, Boston, United States of America.

* Subject list of works on the fine and graphic arts (including photography) and art industries, in the library of the Patent Office. Published at the Patent Office, 28, Southampton-buildings, Chancery-lane, London, W.C. Price 6d.

THE WEEK IN HISTORY.

A Photographic Calendar.

THE historian's task in photography is not an easy one, nor is it one which brings a measure of return for the labour that is spent on it. The difficulty is the scattered literature of the craft. Few English writers have troubled to investigate the early records, and the most painstaking work of this kind must be ascribed to German authors, notably Dr. Eder and Dr. Schiendl. The thanklessness of the task lies in the common attitude, according to which history is dry and the story of the past without relation to the photography of the present day. However, the chips from history which will appear week by week under the heading on this page should convince any one of the incorrectness of that view. There is scarcely a photographic process or a piece of photographic apparatus which is not evolved from the work of the earliest photographers, and many of the "practical hints" which gain spasmodic currency as original appear in the early records of photography in almost the identical words in which they are offered to the present-day reader.

The First R.P.S. Exhibition.

The exhibition to be held next September in the New Gallery will be the fiftieth of a series which was inaugurated on January 4, 1854. The exhibition thus attains its jubilee two years after the fiftieth anniversary of the foundation of the society, for "The Photographic Society," as it was then called, held the first exhibition in the second year of its existence, and since then there has been one year in which no exhibition took place. Perhaps few of the guests at the conversazione, which ushers in the autumn exhibition are aware of the antiquity of the precedent which determines their presence. But the first exhibition was inaugurated in this manner "by a soiree at eight o'clock on the evening of Tuesday, January 3, when the members of the Photographic Society and their friends will assemble to advance and discuss the merits of the collection." Some of the regulations set forth on the announcements do not read so curiously as might be thought. Indeed, were the recommendations as to distinguishing process prints from virgin and untouched negatives to be revived, a visit to a modern exhibition would be robbed of its monotony. To quote from the society's Journal:—

"Negative Photographs on Paper and Glass; Positive Photographs on Paper and Glass, untouched or coloured; Daguerrotypes, plain and coloured; and Stereoscopic Pictures will be admitted for exhibition.

"Coloured photographs will be admitted only when accompanied by a pure and untouched copy of the same Picture.

"Positive Pictures printed from 'touched' or painted Negatives must be described accordingly."

Did the present stylist in mounting exist in those early days? His methods seem to be implied by the request "that, for the sake of economising space, the margin of mounted Photographs should be kept within moderate bounds."

The exhibition was visited by the late Queen and the Prince Albert prior to its public opening, and her Majesty and his Royal Highness expressed their satisfaction at the wonderful advances in photography. The exhibition remained open until the end of February.

It might be mentioned here that at the time this Exhibition was held, Sir Chas. Eastlake, then President of the Royal Academy, was the President of the Society, while Sir Wm. Newton, one of the then finest miniature painters, was one of its Vice-Presidents. From this it will be seen that photography was not then tabooed by artists as many at the present time might think it was. Fuzzygraphs are not quite such a modern idea as some appear to imagine, for about this time Sir William Newton suggested printing through tissue paper to subdue the excessive sharpness given by the lens.

Iron-silver Printing.

One of Sir John Herschel's early papers on the chemical alterations of substances in light dealt largely with iron salts, and the various processes which employ that metal at the present time are based upon his original observations. On January 1, 1862, Emerson J. Reynolds published, in *THE BRITISH JOURNAL OF PHOTOGRAPHY*, some notes on an iron-silver

printing process which are, very likely, unknown to many experimenters with methods of this kind. He coated paper with ferric oxalate, exposed it under a negative, and developed in a solution of ammonio-nitrate of silver. Though he obtained an intense black tone, he found that the picture was often wanting in detail, and this he traced to the solubility of the image (of ferrous oxalate) in ferric oxalate solution. "After a great number of experiments," he writes, "I found that the difficulty might be overcome in either of two ways, one being to substitute the combination of peroxalate of iron with oxalate of ammonia for the plain oxalate, the compound salt not having any action on the protoxalate. The second way was to wash the print immediately on coming out of the printing frame with a solution of acid oxalate of ammonia which immediately formed the double salt referred to."

The double salts of oxalate of iron and oxalates of the alkalis were not used by Reynolds for the first time, but he appears to have done what the previous experimenters did not do—viz., to have shown why the double salt is preferable to the simple ferric oxalate. Silver and iron, the latter as the sensitive salt, have been the subject of much experiment ever since, but until Nicol placed his so-called "Kallitype" paper on the market the method did not come prominently before photographers. Indeed, Kallitype had a short life, commercially, and the principle of obtaining a silver image by the reduction of an iron (ferric) salt is now chiefly applied in the one-solution sensitiser and sensitive materials by which a sepia print is produced on fixation in hypo.

Copyright in Germany.

Twenty-nine years ago, on January 10, Germany passed the Act granting protection to photographic works against unauthorised reproduction. The German authorities do not pay photographers the delicate compliment of officially recognising all photographs as works of art; they have one Act for "works of art" and another for photographs, and the poor photographer fares very badly at their hands compared with the painter or draughtsman. Copyright in "works of art" lasts for the life of the author and thirty years after his death. Copyright in photographs is granted for five years only. This period commences with the end of the year in which the first copies of the photograph appeared, or, if the negative has not been printed from, from the date on which the negative was made.

In conformity with German law every photographic or other mechanical reproduction of an original photograph must bear, either on the picture itself, or on the mounting, the name, or firm, of the photographer or publisher, his address, and the year in which such reproduction first appeared. The German law also holds that it is not piracy to make free use of a photograph to originate a new work, though presumably it leaves it to the Courts to decide whether any "originated" work is new or not.

Legalised Piracy.

But the most notable—perhaps scandalous would be a more appropriate word—enactment is that of Article 4, which rules that "it is not piracy to copy a photograph for use in a work of industry, handicraft, or manufacture." The manufacturer of an overmantel or a matchbox has at his free disposal any photographs whatsoever which he may choose to employ for the decoration of his goods, and the photographer has no redress. The worst form which this legalised piracy has taken is in the postcard industry. The status of the postcard as an "article of manufacture" was upheld in certain German Courts, and publishers began to think that they had "carte blanche" to select any photograph they liked without payment of reproduction fees. But as the picture on the back of the postcard became larger, and the space for the message reached a minimum of a half-inch strip, the card took the character of a reproduction rather than that of a decorated "article of manufacture," and it is questionable whether the law will protect the postcard publishers any longer. German photographers are still agitating against the injustice of the present state of things, and one strong argument in their case is that thousands of cards

* According to the translation of the German Act in "The Law of Copyright," by W. A. Copinger.

never go through the post at all, but are sold simply and purely as reproductions.

The Hand Camera.

In fixing the anniversary of hand-camera photography there is choice among a number of dates. Hand cameras were not unknown in collodion and early dry-plate days, and the name of Skaife is prominent in devising means for rapid exposures. But the era of the hand camera did not commence until a much later date. It began with the "detective" camera which Mr. Thomas Bolas showed towards the end of 1880, and on which he read a paper published in the "Photographic Journal" for January 21, 1881. The camera there described was of box form, with a full-size finder on the twin-lens principle, a focussing scale, and a pneumatic release for the shutter. The lenses employed by Mr. Bolas, if I mistake not, were a pair of stereo-lenses of the Petzval type, working at F. 4. The outside case measured one foot square and five inches deep, and carried inside it thirteen double dark slides.

"When the finder is used," writes Mr. Bolas, "it is generally quite easy to rest the apparatus against a wall, post, or some other firm object, but in many cases it is sufficient to hold the camera in the hands, especially if it be moved in the same direction as the shifting object which one wishes to delineate. In the majority of cases, however, it is altogether out of the question to use the finder, and, in such an instance, one must set the focus to certain fixed points previously determined by experiment and recorded by the simple expedient of driving tin-tacks into the box round the milled head. Thus, for example, when a mark on the milled head is opposite tin-tack number one, the camera is set for a distance of 25 ft. or ten paces of my walking, and in this case distant objects are as sharp as it is generally desirable to have them when a figure forms the leading point of a picture."

Hand-camera workers have no need now to attempt to syn-

chronise the movement of the camera with that of the subject, nor do they work under the condition which prompted Mr. Bolas to advise that "in most cases the camera must be placed on the ground when the picture is taken."

The Twin-Lens Camera.

The use of two lenses of the same focal length dates back to a period much earlier than that of Mr. Bolas's paper. In 1864, if not earlier, a stereoscopic twin-lens camera was used by Disderi a professional photographer in Paris. It was in use before 1864 probably, because a description of it appears in a German work by Disderi, "Die Photographie als bildende Kunst," which was issued in that year, and is described as prepared from a French book by the same author. Disderi employed a primitive form of shutter, consisting of a wooden board moving up and down behind the two pairs of lenses. It could cover either the upper or lower pair, and was attached to the base of the lower camera, in which was the wet collodion plate, by two rubber bands. On the image in the upper camera being judged suitable, this behind-lens board was pulled up by a string. It flew back again on the string being released.

Still Earlier Twin-Lens Cameras.

The above reference to Disderi is the earliest reference in the literature that I have found, but twin-lenses were really in vogue long anterior to any of the dates here mentioned. They were in common use for stereoscopic pictures in the middle "fifties," and, in the early days of the cabinet twin-lenses of the quarter-plate size, were very general for taking the pictures. In 1861 I had a camera so fitted for taking carte-de-visite portraits, in everyday use, and so had very many others. Silvy had his cameras fitted with two pairs of twin-lenses and a repeating back, taking eight negatives on a plate. Silvy was one of the first to take cabinet portraits.

HISTORICES.

ARTISTIC LENSES.

In "Photograms of the Year 1904," in the opening article by Robert Demachy, entitled "Pictorial Photography in France," there occurs the following passage:—"Major Puyo's private exhibition, which opened a few days after the close of the Salon, was meant to be a practical demonstration of the qualities of certain lenses for artistic portraiture, the curves and corrections of which had been calculated by M. de Pulligny and Major Puyo. The pictures taken with these lenses were printed straight on Ilford paper, so as to show clearly the various effects furnished by the new studio telephoto lens, the chromatic single and double meniscus combinations, etc., working at F/10, F/7, and F/5.

"The softness of Major Puyo's pictures is extremely pleasing. There is no actual blur, no disagreeable fuzziness; the accents are strong and well-defined, the depth of focus quite exceptional, and the indescribable mellowness of the image I have never seen equalled. But the cost is so ridiculously small that I suppose the Pulligny objectives will have but small success amongst amateurs. Several of the foremost Parisian opticians and a quantity of professional photographers visited Major Puyo's studio, and were very much struck with his successful results."

I was struck with this passage, because, although a somewhat diligent student of foreign literature, I could not recollect any previous reference to the Pulligny lenses, and M. Demachy's reference is delightfully vague. As luck would have it, however, in the "Deutscher Camera-Almanach" for 1905, the first issue of a new annual edited by Herr Fritz Loescher, and published by the well-known house of Gustav Schmitt, of Berlin, a copy of which has just reached me, I find an original article by Major Puyo on these very lenses, and the following somewhat liberal translation of that article explains the whole thing.—E. J. WALL.

1.—The Artistic Lenses Should Draw Synthetically.

When one hears certain statements and reads certain writings, one might believe that the photographic apparatus possesses the power of making pictures which can convey to our eyes the sensation of nature and life. The exact opposite is the truth; the lens is like the mind of a notary, who grapples with the facts of a case, and an inventory is not literary work.

The lens is in reality a tool for analysis, the photographic reproduction is analytical, whilst all true graphic arts make towards synthesis as their natural aim, because they suggest more than they describe. Advances in art thus succeed by the expression of a greater and greater synthetic reproduction. A commonplace truth, which is clearly evident when one pits a Velasquez against a Mantegna, a Corot against a Claude Gellée.

Therefore the lens, which copies a map so well, gives us no true picture of a tree or a face. No; the tree cut out of zinc, which the lens shows me, is not the same tree which I saw living and breathing in the light breeze; this legion of absolutely identical leaves, which appear to assiduously challenge me to note each one, is not so numerous as it there appears; the lens must have done something to it, in the same way as on this face it has drawn wrinkles, spots, and blemishes which my eye has never noticed, for it was employed in other ways, charmed with the play of lights and shadows in the deep and raised places. Because it is too exact and too impartial, the lens does not draw likenesses.

One must strive for simplification and exercise restraint. At all stages of the photographic work of art the ever-restless striving after a more and more synthetic and impartial form of expression makes itself felt, as soon as one will create pictures in which the documentary qualities shall be sacrificed to the esthetic. These qualities are opposed to one another, and to combine them in the same picture is assuredly to make futile labour. How far can one go in this way towards synthesis? This is another question. The future will teach us; meanwhile, it must suffice for us to prepare for the future.

The photographic work of art is completed in three stages,

by the action of the coloured circles, the details without importance being obliterated. Thus, for example, on a face the freckles disappear.

3. As the breadth of this diffusion circle is proportional to the absolute diameter of the diaphragm, the chromatic softness of the drawing with objectives of equal ratio aperture is in exact ratio to the focus. The result of this is that the synthesis will increase with the size of the picture.

All these peculiarities are of advantage.

IV.—Conclusions.

M. Pulligny, of the Photo Club of Paris, two years ago laid down the principle of the "anachromatic" lens. He will very soon publish a complete work on this subject.

As regards myself I have used for two years:—

1. A plano-convex lens of crown glass, which is specially suitable for studies of heads. It has a ratio aperture of F.5.
2. A simple meniscus, a concavo-convex positive lens for studies in rooms, with a ratio aperture of F.10.
3. A symmetrical objective of two identical meniscuses of

crown glass. The details of curvature of the image and lens distance I have empirically determined. This objective gives with ratio aperture of F.5 very homogeneous pictures.

4. A telephotographic lens, with this symmetrical lens as a positive and a plano concave lens, also made of crown glass as the negative element. With this lens one can obtain heads in life size at a distance of four metres.

M. Pulligny has constructed another series of lenses which he calls "semi-anachromatic," in which the chromatic aberration, is correspondingly reduced.

One of the principal advantages of all these lenses is that without great expense one can use lenses of very long focus; the price is in fact nominal. These lenses enable the amateur to observe the laws of perspective. He will soon discover that the foci of the anastigmats are ridiculously short, and will, following my example, and use foci of from 80 to 100 cm. Above all, with these lenses, actual portraits can be made, heads in half, three-quarter, even of full life size, heads of broad modelling—thanks to the chromatic aberration—and of true "painter-like" impression.

NOVELTIES AND SPECIALTIES.

OCCASIONALLY a revolution takes place in photography, as when the dry plate was introduced, or a successful rival appeared to defy albumen paper. But more change has been wrought in work by steady and gradual evolution than by the few epoch-making introductions. Let any photographer compare a dozen prints from a leading studio of to-day with the same number from a studio of 1870. The difference between the two selections is tremendous, but it has been arrived at by a slow and gradual—almost imperceptible—change of ideas and fashions. If a selection from each of the intervening years could be assembled there would be little difference between any one year and the one succeeding it; but the difference between the first and the last is great enough to be called a revolution—though arrived at by a very gradual evolution.

The evolution has been a broadening one. Thirty-five years ago a photographer, in ordering his mounts, merely wanted so many G.B.E. gold-blocked carte-de-visite mounts, and so many ditto ditto cabinets. About twenty years ago—more or less—Christmas mounts were put on the market. They were still gold-blocked G.B.E., but printed with an appropriate motto. To-day the unity in mount design has vanished; and as for Christmas mount designs, their number is legion. Some workers, perhaps, sigh for the old days when one photograph in all respects resembled another, but most photographers accept the present condition, and use the large variety offered them as a means to increasing their business.

This is an age of

Severe Competition.

and the photographer who quietly sits down and waits for business to come to him is likely to find that his trade is dwindling, and to think that photography is played out. The man who is always to the fore with good work and new ideas earns the reputation of being alert and up-to-date, and he finds this a very valuable asset in his business. Being alert does not necessarily mean squandering money. Many a photographer pays for circulars or newspaper advertisements when he might just as well give the money to a benevolent institution for any good it does him. When the alert man spends money for anything he gets his money back with interest. He may pay an extra three shillings a hundred for some special mounts, but he gets an extra shilling a dozen for the pictures sold on them. It is not so much a matter of spending money as of using brains. Any one (who has it) can get rid of money, but there are comparatively few men who know how to make the most of things without paying for it. It is not always necessary to seek for some new idea to attract customers. New ideas are not numerous, but there are many ideas which are as old as the hills, but which may be new to those who are not professionally connected with photography.

The Art of Being Different.

is a simple one, but if properly cultivated it brings in money. The man who first announced "all pictures by the instantaneous

process" was not, possibly, strictly truthful, but he struck a good idea at a time when there was some slight truth in the venerable joke associating the photographer with the dentist. The words are still often seen, though they have lost their point as the public have become more and more familiar with the ease of modern photography. They did not cost a farthing to the man who first wrote them up against his studio.

In a certain road in suburban London there are four photographers, and in each case their display, so far as it affects the passer-by, is limited to a showcase. The showcases are as mundane and expressionless as four peas. In three of them the work has not been changed for at least six months (in one of them the prints have been carelessly made and are discoloured). In the fourth some new prints were put in just before Christmas. In each instance the work is just the ordinary work of the studio, arranged with a view to showing as many pictures as possible. Here is a chance missed. If one of these men could in some way make his display distinctive it would at once catch the eye of the people for which it angles. Suppose, for instance, that one of the cases was swept and garnished—the glass polished and the red plush well brushed. Then, instead of the sixteen crowded cabinets there is placed in it a single platinotype print of an effective, pretty sitter, the print neatly framed. The change from the ordinary display would be sufficient to catch the eye of hundreds who passed, unseeing, every day. And this is what the showcase is for, and it would be achieved without the outlay of a single extra penny. This one photographer would reap a benefit which to a certain extent would be at the expense of the others. Suppose that all four of them simultaneously woke up, and each woke to an equal degree, would they not do just the same amount of business as when they were all in the rut? Not necessarily so. Enterprise does not merely seize a share of existing business, it

Creates New Business.

is a good business bringer. This need not be a new thing, if it taste of tea. And the tea growers and tea merchants are contemplating a campaign against France, not to scramble for the present tea trade, but to create new trade. So it is in photography, or in any other line of work. It is safe to assume that if those four showcases all attracted attention, some people would be drawn into the studios who had not previously thought of being photographed. There was an old notion that being photographed was a duty one owed to posterity, and the notion does not seem quite dead yet, especially among men. Women are better in this respect, and they may come to the studio because they have got a new ball dress, or a new set of furs. It is time that the posterity notion was utterly exploded, and it will be done by photographers keeping abreast of the times—or a little ahead.

A Good Specialty.

is a good business bringer. This need not be a new thing, if it is a good thing. Some of the commonest special lines are en-

largements, or a cabinet print included with half a dozen cartes. What the specialty should be depends upon the class of trade done, and upon other things. The introduction of platinum prints was at one time a good move. Now they are a regular part of the work of almost every photographer. One of the most effective of specialties I ever knew was offered by a photographer doing a very cheap class of work. In every dozen prints he included one opaline. The glass was a spoilt negative, carefully cleaned, and he bound the edges in passe-partout fashion with gilt paper. A backing card and a tape to hang it completed the work. Not a particularly brilliant idea, perhaps, but, beyond the slight added work, the extra cost of each opaline was less than a farthing. He had nothing to lose, and a few shillings to gain, by his specialty. One of the daintiest of specialties is a miniature portrait. Frames for miniatures may cost a few pence or they may run through shillings to almost any price. A cheap "miniature" may be made by trimming down one of the prints of an order for cabinets, but such a print is in no true sense a miniature. It may, however, prove a small business bringer. The man who poses his sitter ostensibly for a miniature, and can obtain pleasing composition and delicate detail in a small oval space, should make a leading line of this class of work at remunerative prices.

This article is

Merely Suggestive.

There are many special lines, many little novelties, which will occur to any photographer who gives a few minutes' thought to the subject. He need not seek for any great thing—there is no panacea needed for photographers at large. What he requires is something that the people have not seen, or not seen lately, something that will attract attention to the studio. It may be a novelty costing money, or it may be one entailing only a little extra work. In either case, judiciously handled, it should achieve the desired end of drawing custom to the studio.

ALEXANDER BRADFORD.

Photo-Mechanical Notes.

Advances in Photo-Lithography.

Two new processes are at present attracting attention in London, and both are photo-lithographic.

One, that of Messrs. Frey and Son, of Zurich, consists in taking an ordinary photographic negative and then printing on to a lithographic stone or zinc or aluminium plate, which has first been coated with a special bitumen solution. After exposure, which has to be rather considerable—15 minutes—the plate is developed, and the image now shows a reticulation due to the nature of the bitumen solution. The stone or plate is then slightly etched, washed out, and printed as usual in lithography. The printing on the machine from plates so prepared has recently been demonstrated in the workshops of Messrs. Hazell, Watson, and Viney, of Kirby Street, Hatton Garden, and a good selection of work of all classes done in this way has been on view.

The other method is that of Mr. F. W. Sears, of Clerkenwell Green, who relies upon the ordinary crossline screen for obtaining the necessary grain. By some method not yet disclosed, but for which he has applied for a patent (No. 10,855 of 1904), and which he states is extremely simple, he entirely joins up the dots in the extreme high-lights of the screen negative and so gets no image there when printing on to stone, zinc, or aluminium sensitised with bichromated albumen as usual in making direct photo-lithographic prints.

The great claim of both these processes is the accuracy of reproduction obtained by photography and the saving in cost by the elimination to a large extent, if not entirely, of the lithographic draughtsman! Both methods have been applied to colour work; Mr. Sears specially endeavours to produce results entirely mechanically in three-colour. Messrs. Frey, however, are not limiting themselves to three colours, but show some results in as many as 10 to 15 printings. Both processes are interesting as showing the steady progress of photography into the domain of illustration; soon, apparently, all and every kind of reproduction will utilise photography to a greater or less extent; it

certainly looks as though in future even lithography will have to be described as photo-mechanical work.

Regarding opaque high-lights, many methods have been indicated for making the high-lights in a crossline screen negative perfectly opaque so that no dots print there. Mr. Austin, in an article in the "Process Year-Book" of 1903-4, described a method he had invented for sensitising the plate and giving a second short exposure in perfect register on the same negative without the screen in position. Others have suggested racking the screen out after a portion of the exposure has been given. The simplest method, and one entirely successful so far as negatives for photo-lithography are concerned, is to use a rather small stop for the shadows, say, one having a diameter of only one-ninetieth of the camera extension, and then use for not more than one-twentieth of the former exposure a very large stop, say, of a diameter somewhere between one-twentieth to one-thirtieth of the camera extension. If this does not join up the lights sufficiently, then an even larger stop must be used. The point to note is that only a very brief exposure must be given with such a stop, otherwise some effect will be shown on the middle and lower tones, which is undesirable. If, at first sight, after developing, the negative does appear correct, nevertheless until considerable experience has been gained, it should be intensified with copper-bromide and silver, or, better, lead ferricyanide, followed by ammonium sulphide or sodium sulphide before judgment is passed, as it is very surprising sometimes how much the dots will join up on intensification, particularly with the lead intensifier.

The First Photo-Engraver.

Process workers in America look—and not in vain—to the department, "Process Engraving," conducted in the "Inland Printer," by S. H. Horgan. Mr. Horgan has been "in" the illustration movements in the States, and has led one or two of them, so that in matters of practice he is able to dispense monthly counsel to his anxious inquirers. In the current issue of the "Inland Printer" he probes the historical depths of his craft, and reproduces the portrait of the Cardinal d'Amboise, of which Niepce made an engraved plate about the year 1828. He says that the original of this first engraving made by photography was in the museum at Chalon, in France, but "to-day it cannot be found." The present writer is not aware how recent a date is implied by "to-day," but he can vouch for the fact that in July, 1903, not only the plate, but the original engraving, still translucent from the oiling to which Niepce subjected it, as well as several proofs from the plate, were in the public *musée* of Chalon, in which the Niepce relics are collected. And, so far as the writer is concerned, they are there now.

Students' Work at Bolt Court.

An exhibition of the work of the students in the art and process classes of the London County Council's School of Photo-engraving and Lithography, was opened for a few days last week on the premises of the school in Bolt Court, Fleet Street. The work consisted largely of studies and designs from the art classes and the Sketch Club, notable among which was a large poster design, by E. A. Cox, which Mr. Tree ought to have when he bills "The Tempest" through the provinces. The process work includes some very good half-tone in monochrome and three-colour, and some excellent photogravure. But collotype makes a poor show, suggesting that Bolt Court is not training the men who will help to bring the collotype industry into this country. One piece of half-tone is deserving of special note for the way in which two inks, roughly complementary in colour, are used to give the effect of a third printing in black.

Among the process exhibits is a series of photographic charts, showing the absorptions of various dyes employed in making filters for the tri-colour process. These embody the results of a series of unpublished experiments made to ascertain the character of the dyes and the effect of dilution on the absorption. The tests were made by producing an almost normal spectrum of the arc light on an orthochromatic plate, the plate in most cases being the "Lumière C."

The dyes were used in a glass cell of 1 c.m. internal thickness, and the concentration of the solution in milligrammes per cubic centimetre is stated in each instance. The most interesting example is the case of potassium bichromate used to cut off ultra-violet. The most suitable dilution for this purpose is found to be 1 m.g.m. per c.c., and the bichromate, we are told, was preferable to quinine sulphate in being applicable to a dry gelatine filter, in which state quinine was found to be wanting in its absorption of ultra-violet. But it may be strongly queried whether such a filter of bichromated gelatine would keep unaltered for any considerable time, even in the dark.

Cleaning Half-Tones.

Do not use an acid or strong alkali in an endeavour to clean hardened ink out of old half-tone plates (writes "C. H." in the "Inland Printer"). Either will corrode the zinc. The solvent for the ink must be something that will not affect the metal. Such a solvent is benzene (sold as benzole by the druggist). If the metal is warmed and then turned face down in a flat tray, containing just enough benzene to keep the face of the cut covered, it will soften the ink, so that it can be afterwards cleaned out with fresh benzene and a stiff brush.

Printing Plates Direct from Drawings and Tracings.

A process which promises to find a place for itself among those requiring a fairly large number of copies from some drawing, tracing, or line sketch, has been patented by Klimsch and Co., of Frankfurt-on-Main (English patent, 3,608, 1904). It is capable of multiplying such originals as these much more rapidly than the various "blue" or iron processes, while at the same time demanding no high degree of skill, so far as can be gathered from the description in the patent specification. The process is photographic, the sensitive material consisting of bichromate of potash, combined with gelatine, or other similar body. An aluminium plate coated with the mixture is printed from the drawing and developed in the usual way, the unexposed portions washing away. At this stage the plate is prepared so that an ink will adhere to the unexposed parts, the lines of the drawing. The treatment for aluminium plates is with dilute nitric acid, for zinc, bisulphite. This preparation of the plate is the first item, for which protection is claimed. The second is for the use of a yellow screen when exposing. "When the original design is coloured, screens of different colours are placed in front of it when exposing, such colour or colours being selected according to the colour which it is desired to print; the sensitiveness of the plate to one or all of the colours can be enhanced by the addition of suitable dyes." "By placing a screen in front of the design or between the design and the plate, or by using a grained plate, gradations of shade may be reproduced."

We have seen a number of proofs taken from these plates in the lithographic press, which speak well for the ability of the process to deal with originals in very fine lines.

A series of handbooks (in French) on photo-mechanical and allied subjects is issued from the office of "Le Procédé," Boulevard du Montparnasse, Paris. The third of the series (which numbers twelve in all) is reviewed this week under "New Books." The other handbooks treat of the preparation of the original, collodion emulsion, printing, etching, photo-litho, collotype, photogravure, and tri-colour.

"Process Workers' Pocket Book and Diary for 1905." Published by A. W. Penrose and Co.

In addition to a diary, with a space for entries for every day in the year, this strongly and neatly-bound volume contains the chief "facts, figures, and formulæ" of photo-engraving, conveniently classified for

rapid reference. These include rules for copying and enlarging, exposure notes, screens, distances, and exposures with screens and standard formulæ for developers, colour-sensitisers, and etching preparations. As no price is stated, we assume that Messrs. Penrose will send the diary to any process man who applies to 109, Farringdon Road, for it. It is a volume worth possessing, and the editor, Mr. William Gamble, will probably gain the thanks of those in the photo-mechanical crafts for his careful labour of compilation.

Applications for Patent.

Photomechanical Screens.—No. 27,694. "Improvements in screens for photomechanical reproduction processes." Ignatz Bernard Herbst, 1, Great James Street, Bedford Row, London.

Reproduction of Engraved Printing Plates.—No. 27,758. "Improvements in the reproduction of engraved printing plates." John William Mackenzie, 40, Chancery Lane, London (Arthur Leslie, United States).

Half-tone Screen.—No. 27,759. "Half-tone screen with marked off tone fields." Theodor Dittmann, 40, Chancery Lane, London.

Patent News.

The following applications for patents were made between December 19-24, 1904:—

Enlarging Easels.—No. 27,671. "Improvements in photographic enlarging easels." Walter Chas. Grubb and Albert Nixon, trading as The Camera Construction Company, Eagle Works, Durham Grove, Hackney.

Printing and Developing Apparatus.—No. 27,719. "Improvements in or relating to apparatus for use in printing or printing and developing photographic papers and plates." Alf. Julius Beul, 111, Hatton Garden, E.C. (Alfred Brückner, Germany).

Photographic Cameras.—No. 27,740. "Improvements in and relating to photographic cameras." Ferdinand Nusch, 81, Holborn, London (Messrs. Plaubel and Company, Germany).

Lenses.—No. 27,743. "An improvement in lenses." John Edward Evans-Jackson, 19, Holborn Viaduct, London (The Scientific Lens Company, United States).

Reflector Hoods.—No. 27,768. "An improved hood for reflector hand cameras." Arthur James Gray and Samuel Dunseith McKellan, 32, Robert Street, Upper Brook Street, Manchester.

Photographic Cameras.—No. 27,867. "Improvements relating to photographic cameras." John Stratton Wright, 7, Southampton Buildings, Chancery Lane, London.

Photographic Cameras.—No. 27,903. "Improvements relating to photographic cameras." John Stratton Wright, 7, Southampton Buildings, Chancery Lane, London.

Washing Plates.—No. 28,100. "Device for washing photographic plates." Moritz Schlüter, 65, Chancery Lane, London.

Projection Lanterns.—No. 28,227. "Improvements in lanterns for projecting and enlarging purposes." Leo Kamm, 27, Powell Street, Goswell Road, London.

View Finder.—No. 28,237. "View-finder for photographic cameras." Wilhelm Trappiel, 65, Chancery Lane, London.

Photographic Cameras.—No. 28,249. "Improvements in and relating to photographic cameras." La Vége Société Anonyme de Photographie et d'Optique, 52, Chancery Lane, London. [Date applied for under Patents Act, 1901, December 24, 1903, being date of application in Germany.]

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

Magnesium Light for Photographic Printing.—No. 2,693, 1904. J.

Hewitt and E. B. Mills claim protection for a rod tipped with a magnesium composition, either with or without the addition of an igniting mixture. As suitable illuminating mixture they mention magnesium powder, mixed to a cream with an alcoholic solution of gum shellac in the proportion of, say, three ounces of shellac to a pint of spirits of wine. This light is suggested as convenient for the printing of lantern slides and bromide prints.

Panoramic Cameras.—No. 21,830, 1904. (The Multiscope and Film Company, Burlington, Wis., U.S.A.)

Relates to improvements in panoramic cameras and refers more specifically, first to a shield or screen for cutting off more or less of the film to the exposure of light passing through the lens and thereby regulating the length of the negative; second, to a mechanism for controlling the swing of the lens-holder in a manner to provide for time or instantaneous exposure, and, third, to an improved mounting for the lens-holder whereby it may be raised or lowered with respect to the film support and to other features of the holder and its light cone. Among the objects of the invention is to provide an improved device for limiting or determining the length of exposure of the film and thereby the length of the negative produced, and a further object of the invention is to improve the construction and operation of the other parts of the camera mentioned.

Triple Plate Holder for Colour Photography.—No. 22,077, 1904. A

special form of frame to contain three plates which serve successively for colour photography, each plate being arranged in its plate-holder with its special colour-filter, and the plate-holders being arranged so that they can turn and be successively lowered into the chamber of the photographic apparatus when the plates which they carry have been successively exposed. The first of the six claims is for "a negative frame for colour photography the arrangement of three plate-holders in a case and mounted so as to be able to turn upon a horizontal spindle which, in the case of the first plate is a fixed spindle, and in the case of the two other plates, trunnions adapted to be displaced in order that the sensitised plates may also come into the required position at the proper moment, springs arranged behind the last plate-holder tending to push them all forward."

Sensitised Plates for Colour Photography.—No. 22,986, 1904. (A.

Lumière et ses Fils, Lyons, France.) The process recently described by MM. Lumière in these pages, in which a layer of coloured grains is interposed between the sensitive coating and the glass. The coloured grains are grains of starch, ferments, leavens, bacilles, pulverised enamels or other pulverulent and transparent materials, they are coloured by means of colours also transparent, in red, yellow, and blue. The grains of these different colours are mixed in the state of dry powder, as intimately as possible and in such proportion that being applied on the glass as is about to be described, they do not communicate to the entire surface of the plate any appreciable coloration. On one of the faces of the glass is spread a coating of pitchy matter on which is projected the mixture of coloured grains which is brushed in such a manner that the grains which remain fixed thereon touch each other without being superposed and form a layer as uniform as possible. A second coating of pitchy material is then spread, upon which is projected, in the same conditions as the first, a second coating of coloured grains; the whole is finally covered with a varnish. This varnish, as well as the pitchy matter in which the grains are contained, should have an

index of refraction as near as possible to that of the coloured particles, in order that the light may pass through the screen coating without being diffused. The screen coating thus obtained is composed of an infinity of small elements the colour of which depends on the chance of the superposition of coloured grains in the two coatings, these elements will be red, yellow or blue everywhere where two grains of the same colour shall be found superposed, they will be orange, violet or green, everywhere where the two superposed grains shall be of different colour. There will therefore be formed on the entire surface, a quantity of small elementary surfaces possessing one of the six colours stated above. Above this screen coating, is spread by known means the sensitive coating, and the plate thus obtained can be preserved as an ordinary plate until the moment of use. When one of these plates is exposed, the back turned to the object glass, the luminous rays must traverse the screen coating to reach the sensitive coating; it will be understood that a red ray for example will be able to traverse the screen coating only in the parts which are red or which contain red, and that it will be completely stopped by the complementary colours of red. It will be the same for all lengths of undulations and the sensitive coating will be affected at each point of its surface with an intensity which depends on the constitution of the luminous pencil concurring in the formation of the picture at this point, and of the colour of the particles which this pencil must traverse to reach the sensitive coating. After development, the silver reduced in the sensitive coating will mask the different coloured elements of the screen coating, in degrees corresponding to the colour of the light at each point, and the plate seen by transparency will show a picture the colours of which will be complementary to that which it has received on the exposure to light. To restore the normal order it will suffice to invert the negative by any of the known methods.

Triped Stands.—No. 23,814, 1904. (Alphonse-Marc Phalempin, Paris.)

Improvements in telescopic camera stands to dispense with springs and to provide for the release of all parts, by the release of one of the parts of an extended leg. The claim is for "means for securing and releasing each leg section comprising one or more curved locking bolts mounted in a plug in the upper end of each of the sections, bolt engaging grooves or recesses in the lower ends of said sections operating the locking bolt of the lowest leg section by hand and projections on the plugs of the other sections for operating the locking bolts of the said other sections successively as the parts are pushed one in the other substantially as described."

THE interment of the remains of the late Rev. John Mackenzie Bacon, balloonist, scientist, and lecturer, took place on the 29th ult. in the presence of a large gathering, at Swallowfield, near Reading, the body having been conveyed by road from Mr. Bacon's residence, Coldash, near Newbury, about twenty miles distant. In addition to the immediate relatives, who included the widow and grown-up son and daughter, there were also among the mourners many scientific friends, and a deputation from the Guildhall Club, of which Princess Christian is chief patron, and the deceased clergyman was president. The coffin was carried into the church on the shoulders of six gentlemen who had been associated with Mr. Bacon in his experiments. The service was conducted by the Rev. M. J. Bacon, vicar of Swallowfield, who in the last fortnight has had the mournful duty of officiating at the burial of two of his brothers. Among those who sent floral tributes were Lady Russell, the Swallowfield Royal Astronomical Society, the brothers Spencer (the aeronauts), and the Guildhall Club.

A NEW PRINTING PROCESS.*

In bringing forward a new photographic printing process, based on an entirely new method of working, I think it best to first explain clearly what I have been trying for. If we compare a photograph with a fine engraving, is there not something about the latter that the ordinary negative will not give us in our photograph?

True, the optician can point out the wonderful depth of focus and covering power given by the lens. The plate-maker will try to convince us of the beautiful quality of his film, without any markings or faults. The man who develops the film will prove that he has brought out the utmost on his negative that was given by the light action. We used to think that there was some skill in developing a negative, but now we are told that all that is necessary is to put the exposed films in a sort of mangle and get a little child to turn the handle for a few minutes. Then the orthochromatic expert will tell us that he has given us the true representation of colour by tone. Even with all these advantages, do we not have to acknowledge that there is still something wanting, especially in relation to the pictorial side of photography.

Engraving Effects.

Of course, for small microscopic work, or very small portraiture, the P.O.P. print squeezeed on to glass is unequalled for fine detail, but with architectural and landscape work, or for larger prints, this excessive detail is a positive drawback, for this reason: The flat, even stain of the chemical deposit of the photographic print looks like a beautiful piece of enlarging, whereas the broken tones of the engraving give the effect of atmosphere and breadth.

I know that this defect in the photograph has been recognised for years, and manufacturers, by the use of rough-surfaced papers, or by printing through bolting cloth and by other means, have tried to overcome it. But the false shadows caused by the little projections and cavities on the surface of the rough paper, often do not come in the right places, and the even tones of the print done through bolting cloth are quite different to the beautiful broken tones done by the hand work of the engraver.

So the first thing I am trying to obtain is the same broken grain in the image of my print as that got by the engraver. This I do by using material of different textures in the development of the print.

Tonal Control.

The next thing that I have been wanting to get is the power of being able to alter the tones of a print after it is dry (when we can see better the effect we are getting), such as taking out a high light, altering the depth of a light half tone so as to get a proper balance of light and shade, and especially to get better values in the representation of foreground and distance. We often find that a half tone in the foreground is of exactly the same depth as something in the background behind it, and we cannot see where one begins and the other ends, and there is consequently no effect of distance.

Then, again, when we are printing from a rather flat negative, if we print our shadows to the right depth, the high lights, such as the sky, are printed too deeply. In a case of this kind, with our present printing processes, we are almost powerless. We cannot print in clouds because the sky is already too dark, the only thing to do is to paint out the whole of the sky on the negative first. My experience is that I make a satisfactory job of it about once in fifty times.

I am glad to say that with this process I think I have got over this difficulty, because my film is not like the thick gelatine film of the usual printing processes, but is hard, and short in the grain

(so to speak), like a resin-sized paper, and with a piece of ink eraser I can take out a high light or put in light cloud forms in the sky as I require to suit the balance of lines in the picture. In other words, I can finish my development of the print after it is dry and hard, and can do in a few minutes what would take hours to do if I had to retouch the negative. To show what I mean, I have here a print from a negative in which the sky was so thin that I had never troubled to print from it. These clouds were done in a few minutes after the print was dry and mounted.

My experience is that it is very seldom that we can obtain a landscape negative with the clouds of proper form and depth of tone to suit the balance of lines of the picture. We do not require the cloud forms so assertive as to draw the interest from the landscape, we only want a few light tones in the proper places to complete and give a proper scale of light and shade in the picture.

Handwork on the Finished Print.

I think you will agree with me that to be able to reduce the light tones in a print rapidly and easily, with a certain knowledge of what we are doing, and to be able to lighten the half tones of a background immediately surrounding a foreground object, and thus obtain the effect of distance, will be a most valuable aid to pictorial photography. Perhaps some one will say that it is not legitimate photography. I contend that it is as legitimate as pencilling black-lead on the negative to get the same effect, or of pouring hotter water on certain places while developing a carbon print. All that it amounts to is this, that, due to the negative, certain parts of the print have printed slightly darker half tones than we require. What difference does it make how we reduce this surplus amount of pigment? Whether we rub it away on the dry print with ink eraser, or whether we wash or brush it away while the film is wet and fragile during development. Whether we dissolve it away by chemical reduction, or obtain the same result by retouching the negative, or by local intensification of the negative.

The next difficulty we have to contend with in our existing printing processes is this: In getting a print from an ordinary negative, how often do we find that we get just the right depth of tone in the shadows at the same moment that the lightest tints in the high lights are just visible?

The Negative and Local Treatment.

From a thin negative, when the light tints are obtained, we know that the deepest shadows will not be nearly dark enough. If we attempt to intensify the negative the half tones are intensified at the same time, and that is, as a rule, what we do not want. Practically speaking, the only thing to be done is what photographers call "working it up in black and white." Now, to "work up" or paint the shadows to the proper depth with water colour is painting on a metallic basis of silver or platinum, and even if we do manage to get just the right tint of the print, when first produced, the chemical action going on in the film from the sulphur-etting action of the atmosphere will soon change the colour of the print in patches, especially if the water colour has an aniline or metallic basis. Then, again, a thick film of gelatine is about the worst thing one can have to paint upon to obtain satisfactory results, by any one but an artist with a great deal of experience in this class of work. And there is no doubt that to have to work up a silver or platinum print with water colour, or to have to paint on a film (like gelatine) which will absorb water from the paint brush, can only be looked upon as a makeshift, and is why many have had hopes of the gum bichromate process, because they saw that they would be able to work on a pigment base. Indeed, I am very strongly of the opinion that it is in the direction of some pigment process that

* Paper read before London and Provincial Photographic Association, December 29, 1904.

the photographic print of the future is slowly but surely turning, for everything but the very smallest work requiring the finest detail possible.

Some months ago I was watching two artists at work, the one (working in water colours) to obtain depth and transparency in his picture had to have recourse to the terribly tedious expedient of cross-hatching or stippling the colours separately. The artist in oils was able to put in his subject in light and shade first, and trust to adding glazing colours after, to get the effect required; but he could not get the drawing right, and had to keep altering it. Meanwhile time was going on, the sun was altering the lights and shadows of the trees they were painting from every minute, and when I left them they were trusting entirely to their memories for what they were doing. It struck me that with my process I could get a print, with the drawing, lights, and shadows put in in insoluble water colour that could not be rubbed up when being painted upon. That the broken tones I obtained from the texture of the material used for development would instantly give me the same effect as the laborious work of cross-hatching gave the water colour artist, and by using thin glazing water colours over the shadows, to modify their tone as required, and more opaque colours for the half tones and high lights, I could quickly get a water-colour painting with little trouble.

There are hundreds of people who have a good sense of colour, but cannot draw, and even if they could, they have not the opportunity to spend an hour or so day after day to do a water-colour painting from Nature. But here we have a correct outline, light, and shade to start with, and as to the colours to use, there are hundreds of art postcards to get hints from.

Development in Colour Washes.

This is something quite different from tinting an ordinary photograph. There we have a flat, even metallic deposit or carbon and gelatine film, and the colours have to be cross-hatched over it; but I can get the same effect with my method of development with flat washes of colour.

As I was going to read a paper here, and as I happened to have a print of the Father of this Society, our old friend Mr. Henderson, I thought I could not do better than colour it, and shew you what my idea is.

To get it coloured by an experienced artist would not have been a fair test, so, although I have not done any water-colour painting since I was a boy at school, I decided to do it myself. This is my first attempt with only a few washes of colour, and was very quickly done. It was from a paper negative by our friend Mr. Wilkinson.

I have also here a couple of landscapes, and of one of them a well-known black-and-white artist said that the only thing that led him to think that it was not an ordinary water-colour painting was that the foreshortening and drawing were so perfect. Of course, he did not mean for a moment that the colouring was anything equal to what an artist would do, only that he could not tell it from water-colours put on by hand. And after all, these are nothing but water-colour paintings, the photographic part consisting of water-colour pigment embedded in insoluble gums, which form the ground colour of the picture.

It seems to me that in this process there is the germ of quite a new departure in photographic work, which might be of benefit to the business of the professional photographer, as well as to many friends of the photographic amateur who are fond of painting.

My father used to tell me when I was a boy that if I aimed at the sun I would hit somewhere in between, and perhaps you will think that I am doing a lot of aiming and not saying much of where I have hit.

The Defects of "Gum"

When "Pouncy's" gum bichromate process was revived some years back, I thought at first that we had a most simple and useful process, because we could use permanent colours, and that without any of the trouble of the double transfer of the carbon process. But after I had worked at it for some time, I at last came to the conclusion that to get any certainty of result from gum bichromate, or any similar process—such as "Artigue"—was, practically speaking, hopeless for this reason: The action of light on the bichromate—on the parts of the print where the lightest tints are—is so weak that only the surface of the film is rendered insoluble, underneath which the gum is still soluble. In consequence, there is nothing to hold the few particles of pigment forming these light tints on to the surface of the paper; and the sawdust, brushing, or other means of development removes and washes away these fragile light tints off the paper. I tried everything I could think of to get over this difficulty, and get more stability in the film during development, but without success, and after hundreds of experiments extending over several years, I came to the conclusion that I must start on a fresh basis entirely, and begin all over again.

I saw that the sawdust, brushing, or other methods of development as used for gum bichromate work, must be theoretically wrong. Also that I must get the pigment and soluble gum out from under the portions acted upon by light on the surface of the film in the lightest tints, and get the insoluble parts forming the image pressed down on to the paper by direct pressure on the surface.

The New Process.

From these two deductions as starting points, I have gradually worked out my new printing process.

I found that I must have a film consisting of pigment contained in a vehicle having two totally distinct characteristics, one having the most extreme solubility, the other relatively insoluble, but tacky, adhesive. For the latter I use the gum resins as a type of what is required. But to get something sufficiently soluble has taken me about two years. Of course, I wanted it soluble in cold water, and thought that gum arabic would be just the thing. Well, emulsion makers think they have trouble with gelatine, but that is not in it with gum. There is not only adulteration to contend with through the Arabs adding other gums, but there is also differences of solubility in gum arabic itself. If it comes from the tree on the south side it sets differently to what it does on the north side, due to the heat of the sun, then I understand that differences may be met with when it comes from different parts of the same tree. There is also a very strange thing I have sometimes met with. One gets a piece of gum in with the rest that is rendered insoluble by the bichromates without any action of light, and the first light action is to render it soluble, and then it is rendered again insoluble by further exposure. Possibly this may be due to the tree growing in an iron district, or the gum gets contaminated with some metallic compound. I find that the only way out of these difficulties is to get large quantities of gum, and then most carefully test and sort until I get something sufficiently soluble.

Working Methods.

Now for my method of working. I coat a piece of paper with a mixture of the two gums, the pigment and a bichromate. Dry it, and then expose it under a negative. I then proceed to develop in the following manner. I soak the print in water for two or three minutes, the water softens the soluble gum where the light has not acted and loosens the pigment; then by pressing a dry absorbent material, such as blotting paper, down on the surface of the film, the pressure causes the adhesive resin and the loosened pigment to clog together and adhere to the face of the blotting paper. This is instantly pulled away, leaving the insoluble image pressed down on

to the surface of the paper. The print has then a solution of alum poured over it, to remove the remaining bichromate, and to clear and harden the image, and is then rinsed in water and dried.

To my mind, this is the most simple and interesting process I have ever worked at. We have a permanent image in any colour. No toning; no prolonged fixing or washing; no double transfer; no damp platinum paper; and the greatest gain of all is that by the pressure of absorbent material of various textures we can modify the grain of our image, ranging almost from the fine deposit of a bromide print to the coarse effect of a crayon drawing or water-colour sketch. For instance, the smooth surface of the face of a piece of blotting paper will give one kind of grain, and the rough back surface of the same blotting paper would give more broken tones.

Texture at Will.

I do not think that we can have anything much more simple. All we require is a piece of blotting paper and a solution of alum. The exposed print is soaked in water; pressed on to the blotting paper, which removes the pigment not required to form the image, which image is at the same time pressed down on the surface of the paper of the print. The print is then cleared of the remaining bichromate, and can be dried at the fire.

I am very pleased to have been able to make my new process public at a meeting of this Society. At our old, happy meetings of fifteen to twenty years ago, photography was looked at in quite a different aspect to what it is now. If one published a formula then one knew that it would only benefit others, who prepared their own material.

Now, unfortunately for many reasons, hardly any one troubles to make their own material, so that the only people who would really benefit would be a gang of grasping money-making company promoters, whose only interest in photography is what they can make out of it. I need hardly say that I have met many manufacturers both in England and abroad, who act most honourably and in a straightforward manner, but I have met the reverse.

All one can do now to protect oneself, even while experimenting is to patent one's ideas. This I have done in this case. I have not yet made arrangements for the commercial preparation of this paper, but meanwhile, if any one would like to try the process, if they will write to me at "Avenue Corner," Bexley Heath, Kent, I will be pleased to get some paper coated for them, and they can try it.

HERBERT S. STARNES.

ORTHOCHROMATIC AND THREE-COLOUR MATTERS.*

THE INFLUENCE OF GRADATION ON COLOUR REPRODUCTION.

IN all photography from half-tone subjects, gradation is one of the primary matters for consideration. The gradation, or "values," as its separate items are sometimes called, in an ordinary print is rarely correct, for the negative and the printing process both independently tend to falsification, especially at the ends of the scale, and this doubtless is one reason why low-toned subjects with a small range of lights are often preferred by critical workers, the narrower range giving less possibilities of error. But whatever difficulties of this nature present themselves in ordinary photography, they are much increased in colour reproduction. In this case it is not merely a matter of approximately true values, but also of an equal gradation in the three colours. The effect of colour on gradation becomes, therefore, a question of primary importance.

Wave-Length and Gradation.

A considerable number of experiments that I made in the endeavour to answer this question indicate that an increase of wave length generally results in a greater steepness of gradation, other circumstances remaining the same. That is, that green light gives a steeper gradation than blue, and red steeper than green. This was the general result, but some plates appeared to behave exceptionally. Sir Wm. Abney investigated the same matter independently, and arrived at the conclusion that the least steep gradation is given by the colour to which the plate is most sensitive. My experiments do not allow of this interpretation being placed upon them, but for all practical purposes Sir Wm. Abney's results and mine point in the same direction, namely, that the plate taken through the red screen may be expected to show a steeper gradation than that taken through the green screen, and this steeper than that taken through the blue screen. (The difference between our results is that while Sir Wm. Abney found violet and ultra-violet to give a steeper gradation than the blue, I found it generally to give a less steep gradation.)

Gradation and Three-Colour.

It is, perhaps, hardly necessary to point out the effect of such differences in three-colour work. A steeper gradation means a more

sudden change. If, therefore, the three colours give a good black or grey in the darker tints, the lighter tints will be found to lack the colour represented by the steeper gradation. In ordinary work this would result in a preponderance of yellow or reddish yellow in the lighter tints. Or if the lighter tints are balanced to give a good neutral grey, in the darker tints there will be an excess of blue. Doubtless it is possible to argue that such errors, if not excessive, are not very important, the yellow being covered more or less by the other two printings, and the blue used being so nearly black to the ordinary eye that a little excess is hardly perceptible.

A Desideratum in Plates.

If the plate makers could furnish plates that would give equal gradation irrespective of colour (and this could easily be tested by giving similarly graduated exposures behind suitably coloured screens), then this difficulty would be surmounted. It would remain then to make the three exposures on the same plates, and to develop them together, to get equal gradation in all. The period of exposure of each would then be the only factor in determining its density with relation to the other two.

This would be a step towards the realisation of the automatic reproduction of colour. But there would remain so many imperfections that would need compromises that more exactness in this detail might not result in any very obvious and practical improvement in the print. But, however this may be, it is only by working at each problem separately and eliminating the uncertainties one by one that real progress can be made and perfection approached.

CHAPMAN JONES, F.C.S., F.I.C., F.R.P.S.

PLATES, FILTERS, AND INKS. THEIR RELATIVE IMPORTANCE IN THREE-COLOUR WORK.

AT the invitation of the Editor, who is doubtless influenced by the saying that "in a multitude of counsellors there is wisdom," the statement of the writer's views upon this subject has been written. Without being dogmatic, the writer herein gives his orthodox and heterodox views in the hope that they may perhaps initiate a train of thought in some more capable brain, and thus lead to progress.

The photographic plates, light filters, and trichromatic inks are all of equal importance in making a successful three-colour print, but as

* Two Papers from Penrose's "Process Year-Book," 1904-5.

most attention has so far been directed to perfecting the accuracy of adjustment of the light filters to the plates, it may perhaps be stated that a complete study of the requirements of an ideal set of tri-chromatic inks calls for most attention to-day.

Probably the best way to approach the problem is to consider it as a question of obtaining correct colour negatives or records and reproductions or positives.

Plates and Light Filters.

As the plates and filters are used together in obtaining the negatives, they may be considered under one head, for the filters are only employed as an artifice used to correct the imperfect colour sensitiveness of the plates. If it were possible to make photographic plates sensitive to such particular portions of the spectrum as occasion demanded, then they would be colour sensitised so as to give colour records direct, without requiring the assistance of compensating filters; that is to say, the plates would be manufactured in such a manner that one kind of plate would record the red, another kind the green, whilst the blue record would be obtained on a third plate.

It might be expected that every three-colour photographer would understand the reason for using light filters and the necessity for accurately adjusting them to the plates in use, but experience and literature show that knowledge of this description is far from being common. With this in mind, I venture to explain that the light filters are spectacles used to correct the "sight" of the plate, and therefore it is necessary, in order to get the best results, that they be adjusted to the plates with which they are to be used. This explains why colour sensitive plates, when tested with light filters which have been adjusted to different brands of plates, give unsatisfactory results. The fault really lies with the light filters, which, though they may give good results with those plates to which they are adjusted, cannot be expected to give equally good results on plates possessing different curves of sensitiveness to the spectrum.

It is as reasonable to expect that one person's spectacles will suitably correct another's eyesight as to expect to obtain true colour records upon any kind of plates when they are used with light filters which have not been adjusted to them, but possibly are intended for use with an altogether different brand of plate.

Negatives and Inks.

Considering the problem when thus narrowed down to be one of negatives (plates) and positives (inks), it is my opinion that ultimately the present conception of theoretical perfect inks will be abandoned as incorrect, for the reason that the inks as at present advocated are not actually complementary to the colour records, as is supposed to be the case, for the positive is not a perfect (colour) transcript of the negative; there is an overlap of colour and consequently degradation. The fact is apparent in the absorption curves given in proof of the accuracy of the theory.

The writer attempted to prove the truth of this assertion in a lengthy paper published in "Photography," May 22, 1902, page 354, entitled "The Ideal Inks for Three-colour Photography," which may be consulted by those who are interested in the subject, for the writer still considers his views as stated therein to be correct, and they have not as yet been proved wrong.

Suggestions for Practice.

Though it is always desirable to know the theoretical requirements of any process, difficulties arise in practice which prevent the realisation of ideal conditions, and, bearing this in mind, I think it would be advisable for the process worker to supply the printer with the most suitable inks for use with his blocks. If this were the custom it ought then to be easy to adjust a set of plates, filters, and inks which would give reasonably perfect results with less wastage than at present obtainable.

In adjusting such a set of materials I venture to suggest that the usual procedure be reversed and the following method adopted:—

A set of standard three-colour inks would first be selected possessing as near as was practicable the ideal conditions as laid down in the article previously mentioned. From these inks a colour sensitometer would have to be devised or adapted from one of the methods described by Sir W. Abney, by the use of which it should be possible to adjust a set of light filters to suitable plates, the use of which would enable reproductions in colour to be obtained more accurately and with greater certainty than by the methods at present in vogue. But it is essential that the inks be supplied to the printer together with the process blocks.

ARTHUR PAYNE, F.C.S., F.R.P.S.

Exhibitions.

WISHAW PHOTOGRAPHIC ASSOCIATION.

At this exhibition, which was opened on the 29th ult., Mr. Archibald Cochrane, the judge, made the following awards:—

OPEN CLASSES.

Portraiture and Figure Studies.—Silver medals, A. W. Hill, Shotts, and A. H. Allan, Edinburgh; bronze, George Cleland, Edinburgh; diplomas, John R. Harper, Edinburgh, and N. S. M'Murtrie, Wishaw.

Landscape or Seascape.—Silver medal, Fred. Judge, Hastings; bronze, A. H. Avery, Brighton, and J. Addie, Craignek; diplomas, T. Jackson, Leeds, and J. A. Angus, Edinburgh.

Flowers, Fruit, and Still Life.—Silver medal, E. Seymour, Hatford; bronze, J. Fallow, Wishaw; diploma, J. S. Andrew, Swansea.

Architecture.—Silver medal, W. A. Clark, Birmingham; bronze, Dan. Dunlop, Motherwell; diplomas, S. G. Kimber, Southampton, and A. W. Walburn, West Hartlepool.

Lantern Slides.—Silver medal, H. Wormleighton, Leicester; bronze, W. H. Goy, London, and John Stabb, Torquay; diploma, G. Cleland, Edinburgh.

Any Subject (confined to Federation Associates).—Bronze medals, A. W. Hill, Shotts, and M. Warnock, Paisley; diplomas, James Dunlop, Dan. Dunlop, Motherwell, and W. A. Frame, Glasgow.

MEMBERS' CLASSES.

Portraiture or Figure Studies.—1st, N. S. M'Murtrie; 2nd, R. Telfer; 3rd, T. Peat.

Landscape or Seascape.—1st, A. W. Hill, Shotts; 2nd, J. Addie, Craignek; 3rd, J. Lawson; 4th, T. Peat.

Flowers, Fruit, and Still Life.—1st, R. C. Macdonald; 2nd, A. Ramsay; 3rd, T. Ritchie.

Animals.—1st, T. Ritchie; 2nd, R. Sneddon; 3rd, T. Peat.

Snapshots.—1st, J. Addie; 2nd, N. S. M'Murtrie; 3rd, A. Russell.

Lantern Slides.—1st, J. Fallow; 2nd, N. S. M'Murtrie; 3rd, A. Symon.

Ramble Picture.—J. Lawson.

Illustrating Humour.—T. Ritchie.

EXHIBITION AT SCARBOROUGH.

The Scarborough and District Photographic Society provided an attraction at the School of Art, Vernon Place, during Christmas, in the shape of an exhibition of pictorial and other photographs taken by the members of the society. The pictures, which were framed and hung around the walls, included some exceedingly high-class works by local amateurs, many of which have been exhibited at the Royal and other exhibitions. The exhibition commenced at ten o'clock on Monday morning and was open till December 31, music and an exhibition of lantern slides taking place each evening. The

president of the society, Mr. T. F. Brogden (reports the "Scarborough Mercury"), exhibits a series of Dutch pictures, the most prominent of which is "The Three Graces," a large toned bromide. Two other pictures, one a study of sunlight effects and the other of a lady on the cliffs, are capital exhibits, the latter having received favourable mention at the Royal Exhibition. He also has several little views of old Scarborough, three of which are of portions which have since been demolished. His two gums, "School Time," a picture of Dutch schoolboys, and "The Two Drovers," are also worthy of mention.

Mr. Harry Wanless pays particular attention to pictorial effect rather than minute details, and shows some interesting studies in his light-toned bromide enlargements. Foremost in this group is a snow scene taken within half a mile of Scarborough, depicting a large expanse of country knee-deep in snow, a contrast being provided by some trees and hedges and a stream. It is entitled "Winter." A study of the quaint Staithes Creek shows the pretty effect of sunlight on the water, and is of an artistic character. "A Winter Flood" is another very prominent picture, showing as it does Throxenby Mere when in flood, the reflection of the snowy trees in the water producing a very artistic effect. A sepia toned bromide of a herring-boat and a pretty silver print of a stream at Ayton are both excellent exhibits, whilst a somewhat remarkable composition is shown in a picture of Sandside houses, which have since been removed.

Mr. Chas. E. Wanless shows ten large toned bromide enlargements, five of which are 17 x 23 pictures. One of these "Bempton Cliff," is a very fine specimen, and recently obtained the bronze plaque at Sheffield. It brings out in a remarkable manner the steepness and height of these cliffs, and the effect is considerably enhanced by its being framed in a broad white frame. "A Tide Race in Calf Sound, Isle of Man," is another splendid view, showing the effect of the sun glittering on the broken waves. This exhibitor has several other Manx pictures, and some fine sky pictures, a picture of Scotch salmon fishers at the mouth of the Tweed, taken at 3 a.m., being very effective. Mr. J. Pickering has twelve pictures, the best of which are "The Skipper and his Boy" and "Chrysanthemums." His series of portraits are interesting studies and excellent pieces of work. Mr. A. E. King's chief exhibits are one showing a Scarborough ferry boatman waiting for a fare, and another—a delicate bromide enlargement—showing sunrise on the sands. In this one the sun's rays on the wet sands and water are very pretty. Another very effective picture is one depicting Hanover Road, from Victoria Road, during a snow-storm. The flakes show remarkably well, and the effect is added to by a cab being driven along at the time. This exhibitor shows some which have been shown at the Royal.

Mr. A. H. Robinson contributes four carbon enlargements of panorama shots, size 40 x 12, one of these, "Holy Island Sands," being a beauty. It gives a very pretty view of sky and sands. He also has some matte views which show excellent work. Mr. W. Foster Brigham has a large number of pictures, dealing principally with portraiture. He also shows four light bromides, which include a snow scene, a sunrise, and a mist. Mr. Frank Foster, the secretary, exhibits three bromide enlargements, two of which depict sheep grazing along hedges, the third being a capital study of Lowestoft fishermen painting their boat. Mr. J. E. Clay's chief works are "On the Glisters of the Sun," "A Corner of the Market" (Lucerne), and "A Grey Morning."

Mr. C. H. Collings shows a number of 17 x 23 bromides, including two wave studies, and a study of "A Lighted Gas Lamp in the Valley." The latter is a really good piece of work.

Mr. C. E. Brummell shows five pretty Continental pictures; Miss Folding two carbon prints, the tones of which are very artistic; Mr. H. P. Hopkins two studies of boys, one of which is sure to be

popular. Mr. A. Pulford exhibits five small studies, the principal of which is one of herring girls at work. Mr. E. L. Davis shows eight capital pictures, Mr. J. H. Hargreaves one very nice one, Miss Hanks two Continental ones, Mr. G. Bell five bromide enlargements, Mr. J. G. Megginson four local scenes, Mr. W. Brown one of the tramlines being laid at night, Miss Fox a delightful little picture in a warm, red tone, and Mr. Elgar Chapman, Mr. J. H. Rowntree, and Miss Edith Bolton some pretty ones.

BOROUGH POLYTECHNIC PHOTOGRAPHIC SOCIETY.

THE tenth annual exhibition of the Borough Polytechnic Photographic Society was held at the Borough Polytechnic Institute, London, S.E., from the 27th to the 31st ult. The judges (Messrs. H. W. Bennett and W. Thomas) made the following awards:—Class A.—Landscape: Silver medal, "Early Morn on the Sussex Downs," W. Page; silver medal, "When the evening sun is low," F. W. Gregg; bronze medal, "In Glary Woods," W. C. Gurney; commended, "Solitude," S. Smith, and "Springtime in the Meadows," C. W. Burch. Class B.—Architecture: Silver medal, "The Crypt, Winchester," T. R. Somerford; bronze medal, "The Crypt, Hereford," J. N. Sparr; bronze medal, "Banqueting Hall, Haddon," W. A. Geale. Class C.—Any Other Subject: Silver medal, "Confidences," G. W. Francis; bronze medal, "Still Life," E. W. Burch; commended, "A Morning Prayer," E. R. Bull. Class D.—Lantern Slides: Silver medal, "Gateway, Bodiman Castle," T. R. Somerford; bronze medal, "Into the Sacristy," T. R. Somerford; bronze medal, "The Crypt, Gloucester," E. R. Bull; commended, "The Smith," F. W. Gregg.

FORTHCOMING EXHIBITIONS.

January 12-14, 1905.—Boston Camera Club. Hon. Secretary, H. M. Hames, 65, West Street, Boston.

January 14-28, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

January 20-21, 1905.—South Essex Camera Club. Hon. Secretary, T. Mitchell, 180, Browning Road, Manor Road, E.

January 23-28, 1905.—Lancaster Photographic Society. Hon. Secretary, R. T. Simpson, 21, Cheapside, Lancaster.

January 28-February 12, 1905.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grand-Armée, à Marseille.

January 31-February 4, 1905.—Cardiff Windsor Amateur Photographic Society. Hon. Secretary, Mr. G. Gallon, 37, Hamilton Street, Cardiff.

February 6-11, 1905.—Blairgowrie and District Photographic Association. Hon. Secretary, Wm. D. M. Falconer, James Street Cottage, Blairgowrie.

February 16-18, 1905.—Norwich and District Photographic Society. Hon. Secretary, E. Peake, Rydal House, Earlham Road, Norwich.

February 17-25, Northampton Photographic Exhibition. Hon. Secretaries, E. J. Felce, 83, Adams Avenue, and W. J. Lewis, Harlestone Road, Northampton.

February 21-March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

February 25-March 4, 1905.—Birmingham Photographic Society. Hon. Secretary, Lewis Lloyd, Norwich Union Chambers, Congress Street, Birmingham.

March 4-11, 1905.—South London Photographic Society. Hon. Secretary, H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 7-14, 1905.—Brentford Photographic Society. Hon. Secretary, F. H. Read, Ferndale, Clifden Road, Brentford.

March 20-25, 1905.—The Cripplegate Photographic Society. Hon. Secretary, John B. Parnham.

March 27-April 1, 1905.—Leicester and Leicestershire Photographic Society. Entries close on March 20, 1905. Secretary, R. Warden Harvey, Oriental Cafe, Market Place, Leicester.

April, 1905.—International Exhibition, Genoa. Sec. Gen., Piazza Fontane Marce 18, Genoa.

April 3-15, 1905.—Photographic Society of Ireland. Hon. Secretary, R. Benson, 35, Molesworth Street, Dublin.

April 7-May 8, 1905.—International Artistic Exhibition, Berlin. Director, Herr Franz Goerke, Maasenstrasse 32, Berlin, W.

June, 1905.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

New Apparatus, &c.

The "Uno Mano" Lantern-Slide Carrier. Made by Sharp and Hitchmough, 101 and 103, Dale Street, Liverpool. Price 5s.

The manipulation of the lantern entirely from one side is a point of convenience which the user of the modern small projection apparatus will appreciate no less than the possessor of an old "three-

decker," who has much greater difficulty in reaching the opposite side of his apparatus. Messrs. Sharp and Hitchmough's carrier introduces the new slide and removes its predecessor from one and the same side, and is very little larger than other apparatus of this kind which are much less convenient in use. The slide, when it is in the position for projection is pressed closely into register, and save for the different thicknesses of lantern plates, the carrier will give no trouble in the matter of bad focus. The general convenience and rapidity of the carrier should make it popular among lanternists,

A New Exposure Meter—the Photomètre-Normal. Made by E. Degen, 3, Rue de la Perle, Paris. Price 13s. (16 fr.).

M. Degen does not adopt the sensitive paper method of measuring the light as do the well-known inventors of exposure meters in this country, but he bases his instrument on a principle of extinction after the manner of another French exposure meter—that of Decoudin. In this, however, the light from the subject was cut down in stages by a series of diaphragms, and no provision was made for the coincidence of the actinic effect of the light and the visual effect

on which the photometer was based. M. Degen replaces the diaphragms by a violet screen composed of two prisms sliding over each other, so that their exterior surfaces are always parallel, and they cut down the light to a greater or lesser extent. The subject is inspected through this screen "until it disappears from view and has the appearance of a dark mass in which nothing but the 'high lights' are perceptible. In a landscape this does not refer to a very bright sky or to a white wall in sunlight, etc. When working against the light or in getting a cloud effect, however, the sky must be looked for. In portraiture one must just be able to make out the features." This observation having been taken, the exposure is

read off on a scale for "ultra-rapid," "slow," and "very slow" plates, and for a diaphragm for which the apparatus is set in the first instance. The meter is neatly made, and is supplied in a limp leather case.

KODAK Changes.—Intimation is made of the withdrawal of Mr. Harold Senior from the management of the Harrow works of Kodak, Limited, a position which he has filled for the past eleven years. Mr. A. H. Starnes, head of the emulsion department, is also leaving Harrow, whilst the duties of advertisement manager of the Kodak Co., until lately discharged by Mr. Bernard Alfieri, are being undertaken by Mr. A. W. W. Bartlett, resigned from the secretariat of the Royal Photographic Society.

CINEMATOGRAH Accidents.—At about ten o'clock on Thursday night last week a panic was narrowly averted during a limelight entertainment in St. Andrew's Parish Church Hall, Glasgow. The lantern exploded, and the film at once burst into flame. The hall was crowded by three hundred children and teachers. The latter shouted to the children to remain seated, and the fire brigade drove up as the hall was being emptied, but their services were not required. Fortunately the hall was almost level with the street, and none of the children were injured, although they were greatly frightened.—Another case is reported from Belfast. According to a newspaper report:—An alarming incident, resulting in serious panic, occurred on Monday night last week shortly after ten o'clock, at the close of a cinematograph performance in Ulster Hall, Belfast. The building was crowded with children, and while the last few pictures were being shown the cinematograph apparatus burst into flame. The hall was in darkness, and cries of "Fire" caused the audience to make a wild rush for the doors. Seats were overturned and chairs smashed as the people fought and struggled towards the exits. After the hall had emptied the floor was littered with hats, cloaks, and overcoats cast off in the crush. On the stairs the congestion was very alarming, but eventually these were cleared. Only three persons, one of whom was the operator, whose hands were scorched by the burning films, were injured. Up to a late hour the hall was besieged by people clamouring for friends.

THE Latest Colour Photography.—The time-honoured descriptions of processes of colour photography continue to find their way into the press, and even into technical journals, such as "Work," from which we quote the description of the last newcomer. The "process," like its many predecessors, seems destined for the briefest notoriety:—"Simple colour photography is reported to be the discovery of Rudolph Isenmann, of Newark, N.J., who is said to have produced some most promising effects by purely chemical manipulation in the simplest manner possible. With ordinary printing-out paper, either gelatine, albumen, or collodion surfaced, he claims to have made prints containing blue, yellow, green, and brown, by merely soaking the prints as taken from the printing frames in two successive baths, with a washing between the chemical immersions. He says that the colours find their places with wonderful accuracy. The blue arranges itself in the sky, with white cloud effect, and in the sunlit parts of the water in the foreground, while the water in the shade of the green trees takes up a greenish cast, and the browns and autumnal yellows appear on the leaves, and are reflected in the water in some of the pictures. The arrangement of the colours seems to be natural selection influenced entirely by the density of parts of the negatives from which the prints are made. Mr. Isenmann says that he allows the colours to work out their own progress, and never uses any effort to direct them by hand manipulation. Gold is not used in toning the pictures, neither is hyposulphite of soda in fixing them. What becomes of the free silver he does not say; but he has examples of his colour work which have been made and exposed for six months, and he cannot see any change in the colours."

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Jan.	Name of Society.	Subject.
9.....	South London Photo Society...	{ <i>Photographic Papers, Toning, &c.</i> Mr. Maurice Howell.
10.....	Sheffield Photo. Society.....	{ <i>Hand Camera Work.</i> Mr. T. F. Brogden.

12.....	Watford Camera Club.....	{ Annual Meeting and Election of Officers.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MEETING held December 29, 1904, Mr. Teape in the chair.—A member called attention to the difficulty he had found with the Geka Light fillers for the dark room, which, whilst admirable as to their safety and comfort in working, very soon deteriorated on account of the heat of the illuminant in lantern. Mr. Haddon pointed out that if the lantern be properly ventilated all such difficulty would cease. The products of combustion of the illuminant must be carried away and not allowed to circulate in the lantern.

Mr. H. Starnes read a paper on a new printing process (see page 11), and illustrated the paper with a number of prints by the process in monochrome and in colour, one of the best being a portrait of A. L. Henderson. Prints of architectural subjects gave abundant detail, and, as a test, some bromide prints were mounted alongside prints by Mr. Starnes's method, all the prints bearing out the claims put forward by Mr. Starnes in his paper.

The process is a rapid one, twenty minutes being the time from commencement of operations to the dried print. Full range of tones are obtained, and all methods of control are adaptable. Mr. Mackie was certain that the process was much more practical than gum bichromate, if only on the evidence of the large number of admirable prints shown.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

"ARCHITECTURAL DETAILS" was the title of the lantern lecture given at the first meeting of the South London Photographic Society in their new hall, the lecturer being the Hon. Secretary, H. Creighton-Beckett. Close upon two hundred slides were shown, the plan being to take up a definite section, such as fonts, crosses, doorways, &c., and devote a number of slides to each, giving as far as possible specimens of work from Early Saxon down to Perpendicular times. The lecturer urged members to take up this branch on the ground that it gave a definite aim to their photography, each negative being taken for a reason. At the same time they would have the consciousness they were building up a set of negatives which would always be of interest and possibly of value. The subject could not be touched without adding to our knowledge of our country's history and of the manners and customs of our ancestors.

SOUTHAMPTON CAMERA CLUB.

THE ninth annual general meeting of this club was held on Monday evening, the 2nd inst., at the Clubroom, Mr. G. T. Vivian, in the unavoidable absence of the President, presiding over an attendance which, in spite of the inclemency of the weather, was of creditable proportions. After some twenty new names had been added to the membership roll, the Hon. Secretary, Mr. S. G. Kimber, moved the adoption of the committee's report, the keynote of which was one of progress all round. Among other matters therein, mention was

again made of the extreme generosity of the President, Mr. W. Burrough Hill, in all his connections with the Club, of the many influential lecturers who had appeared before the members, and of the increase of membership during the year from 140 to 161. The social success of the past session was recounted, as was also that of the Club members in the various exhibitions all over the country; while the congratulatory remarks of the judges at the recent exhibition of the Club were referred to with gratification. The report concluded with a hearty expression of thanks to the photographic and local Press, and was enthusiastically adopted by the members. The financial statement, which showed a cash balance in favour of the Club of £51 10s. 9d., together with assets valued at £20, against liabilities nil, was considered extremely satisfactory; and the members then proceeded to the election of officers for the ensuing year. This resulted as follows:—President: Mr. W. Burrough Hill (re-elected); vice-presidents: Messrs. A. Horsley Hinton, G. T. Vivian, Dr. Weston (re-elected), and G. T. Vials; hon. secretary: S. G. Kimber (re-elected, ninth time); hon. treasurer, W. H. Trigg (re-elected); hon. lanternist: G. T. Vivian (re-elected); hon. reporter: F. G. Ryder; and committee: A. E. Henley, T. M. Weaver, W. R. Kay, C. E. Cook, W. R. Williams, H. W. Miles (re-elected), W. J. Goatcher, C. M. Cooper, C. Daw, and C. D. Kay. Votes of thanks to retiring officers and the chairman concluded a most satisfactory meeting.

HACKNEY PHOTOGRAPHIC SOCIETY.

MR. H. W. BENNETT, F.R.P.S., on Architectural Photography, was the attraction at the last meeting of this society. He succeeded in condensing into the short time at his disposal precise information on apparatus, materials, and methods, as applied to this class of work. The following note on testing the capability of a lens for architectural work is characteristic of the thoroughly practical nature and utility of the whole lecture.

Before using a lens in a dark interior the photographer would do well to find out exactly what his lens will do. This can be done out of doors in the following manner:—

Some object, such as a leafless twig, is sharply focussed in the centre of the screen. The camera is then rotated until the twig is near an edge of the screen. If it is not now in sharp focus, the amount of racking in or out necessary to secure sharpness should be ascertained. The size of stop necessary to give sharp focus at the centre and edge of the plate should also be found.

The front of the camera should next be raised so that the twig appears in a corner of the ground glass, and again the stop needed to bring it into sharpness should be noted.

The photographer should also see how far the front can be raised without causing dark corners on the screen.

PHOTOGRAPHY and Forgery.—In connection with the recent forgeries in the City, of Bank of England notes, the "Daily Mail" reports the views of an expert, who says:—"The camera has completely conquered the secrets of the English banknotes. There is no forgery easier in the world than that of the £5 Bank of England note, and yet the authorities still retain the original black and white note, and will not make any innovation. True, there are special water-marks which are not known to the general public, but by photographic processes these are brought out very clearly, thus enabling the engraver to carry on the work of forgery most successfully. In the case of United States notes, the engraving is so minute that it would not print if an attempt were made to reproduce it by photography on steel, and it cannot be printed on stone. The Russian Government has also now established a system of colour printing which is calculated to put an end to forgeries of this class.

News and Notes.

MR. F. O. BYNOE, who until recently occupied the position of manager of the Brookes-Watson Daylight Camera Co., has joined Messrs. W. Butcher and Sons as representative chiefly in London.

At the Holmfirth Photographic Society's Exhibition last week, the premier awards went to J. E. Latham, Manchester, for landscape; J. R. Hogley, Holmfirth, for portrait; and A. Lunn, Huddersfield, for architecture.

THE Northampton Photographic Exhibition, which is to be held from February 17 to 25, has secured the transfer of the English and French Loan Exhibit recently shown at the Cartwright Exhibition, Bradford.

DUTY-FREE Alcohol for Industrial Purposes.—The Committee which is now examining into the use of duty-free alcohol for industrial purposes, this week received evidence from Mr. T. Macwalter, of Messrs. Elliott and Sons, Limited, of Earnet.

In reply to a querist in our issue for 23rd ult., we stated that the half-tone process by Julius Verfassers is published by Messrs. Penrose and Co. In this we were in error, for it is published by Messrs. Hiffe and Sons, Ltd., of 20, Tudor Street, E.C.

UNDER the auspices of the Hastings and St. Leonards Photographic Society a pictorial photographic exhibition will be held at the Public Hall, Hastings, on 11th, 12th, and 13th inst. The borough member will open the exhibition on the first day, while Mr. Harvey Du Cros will present the prizes on the last day.

New Mounts.—From Messrs. H. and W. Green, the "Crown" Photographic Factory, Rotherham, we have received samples of their new "Ebora" mounts of black board, which they issue in cabinet size and for circular prints of various sizes. Another new line of the firm is an 18 by 15 granulated plate-sunk mount with oval paste-down centre for 12 by 10 prints. An oval cutting shape is given free with the first order of these mounts.

MORE than 10,000 prints were sent in to the recent "Graphic" Photographic Competition. These were weeded out by skilled members of the Art Department till 5,000 were left. A second examination reduced the number to 500, and these were submitted to Sir H. Trueman Wood, Mr. Luke Fildes, R.A., and Mr. Carmichael Thomas, who made the following final awards:—First prize: Pierre Dubreuil, Lille. Second prize: W. Northwood, Northwood. Third prize: Wm. McLean, Belfast. Fourth prize: T. Suscher, Geneva.

THE offer of a prize of £50 recently made by the editor of "The World and His Wife" for the best photograph of an interior brought an overwhelming response. The examiners have now completed the consideration of the thousands of photographs sent in, and have awarded the first prize of £50 to Mr. R. F. Tyler, Surbiton, Surrey. Five prizes of £1 each have been awarded to Miss E. Swinburn, Bexhill-on-Sea; Mr. J. U. Young, Sheffield; Miss Ethel G. Lowe, East Ilsley, Berks; Miss J. E. Corrie, Alresford; and Mr. H. Bird, Avonmouth, near Bristol. A portfolio of fine coloured prints has been forwarded to the fifty persons whose photographs came next in order of merit.

ALLEGED Explosion of Flashlight Powder.—Several of the papers last week reported an incident at the Post-office in the nature of an explosion said to have been caused by a package of flashlight powder sent through the post. The explosion occurred in the North-Western Department of the Mount Pleasant Branch of the General Post Office recently. Work was in full swing in the sorting-room, when one of the sorters took up a brown paper parcel labelled for the Midlands. The parcel was about 9 in. long by 4 in. high and wide, and was addressed to a clergyman by a London dealer. The sorter threw

it into the proper basket, and immediately there was an explosion. Windows were smartly shaken and flames shot up from where the parcel fell. General confusion reigned, but some of the officials rushed for the fire buckets, and the flames were put out. An examination of the basket showed that the mysterious parcel had been destroyed, but the remains were gathered up, and from these the officials have come to the conclusion that the parcel contained photographic chemicals. It is thought from the preliminary chemical examination that the preparation was for producing a photographic flashlight. Only two other packets in the basket were slightly damaged.

Correspondence.

* * * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.

* * * We do not undertake responsibility for the opinions expressed by our correspondents.

THE EMPLOYEES' UNION.

To the Editors.

Gentlemen,—There is no doubt that there is a silly season in photographic journalism, as in the outside world. The big gooseberry and sea serpent are still in evidence. To me the perennial talk of an Employees' Union is like one or both of the above-mentioned subjects; and I should have thought that all the previous attempts and the verbiage that has been wasted on this subject would have taught some of us, at least, that the whole thing is moonshine.

Personally, I believe that those who are continually crying out for a union are the incompetents. If, instead of bewailing his fate and cursing his employers, the average assistant were to employ his time in more perfectly learning his business, it would be better for him and his employer.

I have been an assistant for a good many years, and, so far as I can see, am likely to continue in that position for many more, but I do not sit down and wail or grumble at my employer, but continually strive to learn new things and new methods. The result is that I am now more useful to my employer than I was five years ago. He knows it, and shows his appreciation by a better salary and leaving more and more to me. I am not content merely to do what is required of me, but try and introduce new ideas and new things, and I find that pays me better than trying to get up unions, the ultimate benefit of which I am doubtful. —Yours faithfully, A TEN YEARS' ASSISTANT.

London, January 2, 1905.

THE NEW NAMES FOR METRIC MEASURES.

To the Editors.

Gentlemen,—Seeing your apothecary quotations of French weight and measures in your issue of December 30, 1904, brings me to the conclusion that the apothecaries try their level best to turn the whole and simple metric system to ridicule and to just such a silly and idiotic state of efficiency as the present English system.

On the Continent your quotations are by kilo and gramme, by litre and cubic grammes, and nothing else. One kilo is written 1 Ko., one quarter of a kilo, also called half-pound in some places, is given as 250 gr. The same with the smaller units; say half a gramme is given as 0.5, and no Frenchman would know what your chemists means by mils., millilitre and centimils, but would ask for 1 or 0.01 grammes respectively, all will go smilingly. If you go to a Continental chemist giving the equivalent of one minim by asking 5.9192 centimils, he would feel himself justified to give you into safe keeping; but if you asked for 0.059192 cc. he would feel at home and try to give you 0.06 gr., if that quantity can be measured out. All medical quotations are simply given as 1.0 or 0.05, as the case may be. The standard being gramme, all other nominations are looked upon as foreign.

STANDARDGRAMME.

[We publish our correspondent's letter *literatim* and *verbatim*, though we are afraid that the advocates of metric measures will not extract much satisfaction from it.—Ers. B.J.]

Answers to Correspondents.

- * *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.*
- * *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- * *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.*
- * *For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

PHOTOGRAPHS REGISTERED:—

T. S. Robinson, 185 and 187, High Street, Homerton, London. *Photograph of Winter Bathers, Victoria Park.*

J. Jarrett, High Street, Keynsham, Somersetshire. *Photograph of the Meet of the Bath and County Harriers.*

Leo Legge & Co., 117, High Street, Walsend. *Two Photographs of the Rev. Father E. Walsh.*

JUDRAUS HANNA. 1. Penrose and Co., Farringdon Road, E.C., could supply the outfit. Fritz's "Photolithography," translated by E. J. Wall, is a standard work. 2. No. The apparatus cannot possibly help you in any way, and certainly will not save retouching.

HALF-TONE SCREENS.—I shall be glad if you can tell me where I can obtain information on the various kinds of half-tone screens used by process workers.—A. F. L.

"The Half-Tone Process," by Julius Verfasser, published by Messrs. Iliffe and Co., of 20, Tudor Street, E.C.

SELF-TONING PAPERS.—Are self-toning papers and postcards, carefully worked, as permanent as C.C. matt. toned with gold and platinum?—OLD CROW.

There is no reason why papers of this kind should not be just as permanent as those in which the toning substances are applied from a separate solution. And in our experience the results are equally lasting.

INSTRUCTION IN RETOUCHING.—I am writing to ask if you will be kind enough to inform me of a good place to learn finishing in black and white, also in oil and water colours. I might state I have been operating and retouching for some time, and as wages are so bad I want to improve myself. I like the work and feel I should get on, but I want to learn the work thoroughly. I thought you would be kind enough to inform me the best place, through the medium of your paper. —ENQUIRER.

If you will examine the "Miscellaneous" advertisements in the present number you will find mentioned several gentlemen who undertake instruction of the kind.

STAMP PHOTOS WITH ORDINARY CAMERA. I have a half-plate camera with rapid rectilinear lens. I should like to take stamp photos or miniatures, or both. Can I get any additional fittings to my camera to enable me to do that, and what is the cost of same? Thanking you for any information you may be able to give me through your most useful paper.—BRIDLINGTON.

Several repeating backs are sold which might possibly be fitted to the back of your camera. Messrs. Marion, of Soho Square, are the makers of one which we believe would answer your purpose. Also, if the size of the camera front permits of it, you might have fitted a battery of small lenses, such as are used in the usual stamp-photo cameras.

BLACK TONES ON COLLODIO-CHLORIDE PAPER.—I have lately seen some collodio-chloride prints, which were a pure black colour. How are these obtained, and can any paper be used?—F. IZARD.

We cannot, of course, state definitely how the tones of the particular prints were obtained, nor whether all papers are suitable, but we believe so. Any good matt surface paper can be used, and printing should be carried rather further than usual; the prints should be well washed and toned in a borax or acetate gold bath to a purple stage, then thoroughly well washed and toned in a chloro-platinite of potash and phosphoric acid bath, as given in B. J. ALMANAC, 1905, p. 1031, where also another bath will be found.

COPYRIGHT ABROAD.—I have a number of prints copyrighted, some of which I propose offering to a German firm in Berlin. Before doing so I should like to know whether I can safely do so. Does the copyright extend to Germany, or must I get them separately copyrighted there?—TOURIST.

Under the Berne Convention of International Copyright registration in Great Britain and the Colonies entitles the photographer to protection in almost all countries. Germany is one of these. The most notable exception is the United States. Under the Berne Convention you obtain the same protection in each country as the natives of the country, and the copyright law varies in each.

ERECTOR OF STUDIO.—Being twenty-five years in the photographic business, and as I am just starting in business for myself, will you be kind enough to give me full particulars as regards to portable studio. I have a portable studio, size 12 by 8; it can be bolted together. What I require to know is: Can I put it up in my garden, which is over 30ft. long, without applying to the Borough Council? Any further particulars will greatly oblige.—W. JACKSON.

We believe that if the studio is erected direct on the ground it will be classed as a permanent erection, but if mounted on small wheels, or possibly other supports, raising it from the ground, the regulations of a local authority as to buildings cannot be legitimately applied to it.

DEVELOPER.—Although an amateur, I shall be glad if you will let me know what developer I can use instead of metol, one of somewhat similar character, as metol seems to irritate my fingers.—SCOTCHMAN.

This column is open to all and any of our readers, whether amateur or professional. There is a very large choice in developers, but probably adurol would be found quite satisfactory, and a simple formula is: Sodium sulphite, 4 ounces; carbonate of potash, 3 ounces; distilled water, 10 ounces. When dissolved add: Adurol, $\frac{1}{2}$ ounce. For ordinary negative work mix one part of above with five parts of water; and for bromide paper use one to seven, and add a few drops of 10 per cent. potassium bromide to each ounce.

SILVER STAINS.—I find on looking up some old negatives, from which fresh prints are now wanted, that they are smothered with silver stains, although the negatives are varnished. What can I do in the matter?—T. P.

Some of the stains may be only in the film of varnish; anyhow, the first thing to do is to entirely remove the varnish by soaking the negatives in methylated spirit, to which some ammonia has been added. Rub the film, after it has been soaking for some little time, with a tuft of cotton wool, remove to a fresh bath of spirit. Sometimes two or three baths are required to remove the whole of the varnish. Then just rub the stains with pumice powder, and then wash the plate well under the tap, and immerse in a strong and freshly made hypo bath, and leave them therein till the stains disappear. Sometimes this takes hours.

How to VIGNETTE.—Having commenced some enlarging, I wish to know how to vignette an enlarged picture—i.e., where is the vignette placed? Also, will the same sort of vignetting cards used for P.O.P. be suitable for use with the lantern? Also, does the vignette have to be kept moving, etc.—H. B.

Our querist is using a lantern, and, presuming that the space between the lens and sensitive paper is open, there is no difficulty in vignetting. A small aperture of the required shape should be cut very much smaller than the required vignette; in fact, it should be not much larger than the actual diameter of the lens. If this is then placed in the path of the rays of light close to the lens, and kept moving backwards and forwards, a soft delicate vignette will be obtained. The nearer the lens the vignette shape is placed the less it vignettes; and of course, the nearer the sensitive paper the smaller the actual image shown. Care must be taken to use a fairly large card, so as to throw a shadow over the margins of the paper.

PHOTOGRAPHS FOR THE PRESS.—I sent a certain number of photographs to a Press Agency, after their guaranteeing safe return when asked. Some time after I wrote for them, receiving all but a certain number, which they said were out on approval. After waiting, wrote, and finally sent account. I still receive no answer. What is best course to pursue? Can I charge for use, 10s. 6d. each, or can I only charge for value of prints? In any case, how can I obtain compensation, seeing they ignore my letters?—PROFESSIONAL.

The explanation given by the Agency is probably quite correct. Photographs are not always returned punctually by editors. If you do not hear shortly you had better write claiming the value of the prints, which is all you can do yourself, or through your solicitor, unless reproductions of the photographs appear of which you are not notified by the Agency.

NITRATED SUGAR PROCESS.—Respecting your article on page 689 of "Almanac" for 1904, on Monckhoven's "Nitrated Sugar" printing process:—(1) I should be very glad if you would kindly inform me whether, and where, the finished solution ready for applying to the paper can be bought. (2) I have been trying to make "Nitrated Sugar" by using pure sulphuric acid and the ordinary pure nitric acid, and can't succeed. Will you please tell me what is meant by "Monohydrated" nitric acid. Any word of guidance in this matter will be much valued.—CHAS. BURTOFT.

(1) 20 per cent. solution, in alcohol, of nitro-glucose is listed by Merck at 6s. 9d. per litre, though we cannot say whether it is identical with the substance directed by Monckhoven. Indeed it can scarcely be so, as nitro-glucose is a mixture and will vary in composition according to the mode of preparation. (2) Probably an acid corresponding in strength to one molecule of nitric acid and one molecule of water. This means a percentage of real nitric acid of about 80 per cent., and a specific gravity of about 1.46. We should think it unlikely that you will obtain any useful results from the process, as it is one which calls for considerable chemical knowledge.

RETOUCHING.—Please find enclosed four prints, showing before and after retouching. I shall be glad if you will kindly give me your opinion of my retouching and the price I ought to charge for same (say trade work).—J. D.

(1) We consider your work of second-class quality, but extra care and attention to the gradation of light and shade, and the respecting of character and better balance of the shadows, should do much to advance you. Do not so radically remove the indentations between the brows, but retain them sufficiently to give

due force to the likeness. Your modelling is defective; you fill up too much. (2) The usual price to charge for ordinary sized cabinet vig. is from 1s. to 1s. 6d., but a considerable number of trade retouchers, very unwisely, try to demolish one another by quoting most absurd and cutting prices. Some of the old established firms keep up fair and reasonable rates—and justly considering the great importance of good and artistic retouching to the photographer—but many strive for cheapness rather than quality, and so the bulk of the retouching one sees about the country will not bear close examination and analysis. Keep to a fair price, give good finish, and there should be plenty of scope for a smart, well-taught retoucher.

SEPIA PAPER.—In your reply to a reader in last week's "B. J.," you advise the use of a "sepia," or "brown-line" paper, for the copying of drawings and tracings. Can you inform me whether this paper, which you state to be as simple in manipulation as "blue" paper, can be prepared at home with satisfactory results? And if so, what are the necessary solutions?—DRAUGHTSMAN.

A formula which can be worked quite easily is as follows: Make stock solutions of (a) green ferric ammonium citrate, 110 grains in one ounce of water; (b) tartaric acid, 20 grains; water, 1 ounce; and (c) silver nitrate, 45 grains; water, 1 ounce. Swill also 30 grains of gelatine in 1 ounce of water, and keep the mixture fluid by standing the containing vessel in hot water. The sensitiser consists of equal parts of these four solutions. The gelatine is first measured out and A and B solutions added to it, the silver being afterwards dropped in. The mixture is kept warm and applied to the paper with a flat camel's-hair brush. The brush should be held loosely—i.e., just dragged to and fro by the fingers. After drying by artificial light the paper is ready. A faint image is visible on printing, and the remaining operations consist in fixing the print for about two minutes in a weak solution of hypo and in washing in clean water for half an hour.

LUMIERE Plates, Papers, and Films are now marketed at new and reduced prices. Plates are priced at the "popular" figure of one shilling per dozen quarter plates, and the other well-known manufactures of the Lumière N.A. Co. are brought into line with this new tariff. The revised price lists are obtainable from the Company at 4, Bloomsbury Street, London, W.C.

NOTICE.

THE INDEX to the 1904 Volume of THE BRITISH JOURNAL OF PHOTOGRAPHY will be published with next week's issue.

* * NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

The British Journal of Photography.

The Oldest Photographic Journal in the World.

EX CATHEDRA.

"No Cameras." South African society has to be taken severely in hand, if we may judge from the letter of a lady in Johannesburg to the "Daily Mail." On the invitations to Princess Christian's garden-party it was thought advisable to say, "No cameras allowed," with the object of preserving the dignity of the occasion. The incident is said to have given rise to an amusing sequel, for a week later the wife of a retired shopkeeper, true to the imitative instincts of the Colonial, deemed it the fashionable thing to taboo photography, and after "R.S.V.P." on her invitation cards were the words: "White gloves to be worn. No cameras!"

Contravened Heroics. Mr. Kearton and others of his kind must look to their laurels. If a Glasgow photographer obtains his opportunities they will not be alone for long in scaling dizzy heights or hanging by their eyebrows from sea-washed cliffs. Their competitor is unknown to us save through a newspaper report that he has applied to the Glasgow Corporation for permission to ascend by ladder the Scott monument in George Square to obtain a bird's-eye view of the city. The Scott Monument is 80 feet high. The Corporation said "No," and there is thus one photographer in Glasgow who is baulked in his desire to secure public recognition of photography as an exponent of art *in excelsis*.

The Royal Photographic Society. The current number of the Society's "Journal" contains the announcement of a notable change to be made in the regulations of the autumn exhibition. No medals are to

be offered in the pictorial section. In the scientific and technical sections, however, medals will be offered as before, and seven judges will be elected by the members as has been the custom hitherto. The judges so elected will form the selecting and hanging committee in these sections, but a specially constituted committee will perform the same duties in the pictorial section. The step is one with which the President of the R.P.S. is entirely in accord, for, as he pleasantly expresses it, "the substitution of the honour of being hung would change the present lottery to one of all prizes and no blanks." Even if one is not disposed to sum up the difference between the inducements which were and are to be in these terms, it is without a doubt that the withdrawal of medals will not deprive the Society of a single exhibitor, and if it makes possible a more rigorous selection of fewer pictures the step will be proven a wise one.

Errors in Star Photography.

In our issue of December 23, we drew attention to the paper of Professor H. H. Turner, discussing minute errors in photographic star maps. The variations there were in the positions of the stars as recorded in the negative. Now an abstract of a paper by Max Wolf, of the Heidelberg Observatory represents that authority as casting doubt on the photographic records of the brightness of stars. If the original memoir in the "Astronomische Nachrichten" is correctly reported, Herr Wolf finds that the order of brightness of a series of stars may be different in photographs taken at the same instant with a number of lenses of different types. The variations arise from the colour of the light emitted by the star, the constitution of its spectrum, and from the dimensions and construction of the photographic objective. The total effect may be sufficient to make the visual order of brightness of a series of stars different from the photographic order, and Herr Wolf holds that conclusions from photographic evidence of this kind should be withheld until the measurements can be verified by visual tests.

Bromide Prints in Colours.

A few weeks ago mention was made of Herr Gros' recent methods in catatype printing in the way of working from an image of peroxide of manganese, instead of from that of the original silver. This process Herr Gros now proceeds to apply to the production of coloured bromides, without reference to catatype. His directions as set forth in a French patent ought to satisfy the most strenuous advocates of chemical gymnastics in the after-treatment of bromide prints. He treats the print in a solution containing potassium bromide, citric acid, and potassium ferricyanide, as well as potassium permanganate, manganous sulphate, and carbonate of soda, or, rather, the

product obtained on mixing these three compounds. This formidable preparation decolourises the print, which is then immersed in an alkaline solution of potassium ferricyanide. The end is not yet. At this stage the print has been provided with a brown image of manganese peroxide. This is then coloured by any known process—e.g., by aniline hydro-chloride. All of which, it seems to us, is a very long-winded way of producing prints of very problematical permanency.

Photography in the Russo-Japanese War.

A Tokio correspondent of our contemporary, "La Photographie Française" sends to that journal some interesting notes on the use of photography by the Japanese. For some years the headquarters staff of the Japanese Army have been studying the subject, and have founded an Army Photographic Service Corps. Folding film cameras are used, and the films are developed at the rear of the advanced line, and positive films quickly sent to the front. Light bamboo stands are used, and most of the cameras are fitted with telephoto lens, which, however, only give a magnification of eight diameters. Cameras are attached to captive and free balloons, and special orders have been given to the aeronauts to destroy the films and cameras in case of capture. Photography is also used to duplicate the orders and reports of the day and microphotographs of these are carried, it is stated, by the Chunchuses and Chinese under their nails, between their toes, up their nostrils, and even in their stomachs. In the latter case, it is stated that the document is hidden in a small ivory tube, which the porter swallows if he thinks there is a chance of his being captured, the ivory resisting the gastric juices, and thus preserving the document. When the microscopic document arrives at its destination, it is enlarged by projection, and copied, as was done in the Franco-German War of 1870.

* * *

The Changing Times.

Photography, like everything else, moves with the times. As old sources of income fail, new ones take their place. The stereoscopic craze, which began at the time of the great exhibition of 1851, has been so long dead that it is a mere tradition to all but the oldest photographers. Not that stereoscopy itself is dead, however, by any means. The great trade in portraits of celebrities is still with us, but its halcyon days are gone, so far as the stationers' shop windows are concerned. The illustrated magazines have hit it hard, though they are themselves a great source of income to photographers. Time was—and but recently—when American visitors brought much revenue to a few West-End firms; but nowadays these visitors do their posing on their own side of the water. Among the many new fields open to photographers the application of the camera to commercial work for illustrating catalogues may be cited, and the much-smiled-at picture-postcard has turned thousands of pounds into photographic pockets. One of the pleasantest features of these modern innovations is that they bring a little grist to many pockets. The much-lauded fashions of the past were usually for the benefit of a few well-known leading firms. To-day hundreds of photographers share in supplying the widespread demand for new things. To some men it means but a stray guinea now and then, to others it is a small, perhaps, but steady, addition to revenue; while there are dozens of men whose work is almost entirely devoted to meeting these new demands. Probably the photographer to-day makes more money outside portraiture than ever he did.

THE SHOP HOURS ACT AND PHOTOGRAPHERS.

THE new "Shop Hours" Act, 1904, came into force on January 2, and it will be well to consider how it will affect photographers when it is applied, for it is really a question of local option. By it the local authorities can regulate, within certain limits, the time for closing shops or carrying on of any retail trade, except those enumerated in the Schedule—Section 2. The hour to be fixed by the closing order is not to be earlier than seven in the evening on any day of the week, except that on one specified day in the week it may be an hour not earlier than one o'clock in the afternoon. So far as the early closing in the evening is concerned, we imagine that it will make but little difference to photographers generally, except, perhaps, in some few cases it will enable the employees to get off a little earlier than hitherto. It is in the one day a week, the half holiday, that will mostly concern many. It is customary in most districts for shops now to close at two o'clock one day a week—usually Wednesday or Thursday—but that is quite voluntary on the part of the shopkeepers, and many do not close at all. As a rule photographers have not adopted this, and some of them do a fair amount of business with those who are liberated by the early closing. When the new Act is put in force, they will now be compelled to close like their neighbours, or they will be subjected to a penalty of, for the first offence, a fine not exceeding twenty shillings; for the second, one not exceeding five pounds; and for the third and subsequent offences, twenty pounds.

It may possibly be surmised by some that photography does not come within the term "Any retail trade," but we are inclined to the opinion that it does under the Act, inasmuch as under Clause 8, Sub-section 3, the following occurs: "The expression 'shop' includes any premises or place where retail trade (including the business of a barber) is carried on." If it is made illegal for a barber to carry on his business during the prohibited hours, so it would be, we imagine, for a photographer to do so. It seems from the wording of the Act and the circular on it issued by the Home Office, that the local authorities have some discretionary powers in administering it, and possibly some trades may by them be exempted from it, for Clause 4 says: "The central authority may at any time on the application of the local authority, revoke a closing order either absolutely, or so far as it affects any particular class of shops, and, if at any time it is made to appear to the satisfaction of the local authority that the occupiers of a majority of any class of shops to which a closing order applies are opposed to the continuance of the order, the local authority shall apply to the central authority to revoke the order in so far as it affects that class of shops." From this it would seem that the local authority have the power of exempting certain businesses where a majority of those who carry them on are opposed to the early closing of them.

It may be interesting to give the businesses exempted from the Act in the Schedule. They are as follows:—Post office business, sale of medicines and surgical appliances, sale by retail of intoxicating liquors, sale of refreshments for consumption on the premises, the sale of tobacco and other smokers' requisites, the sale of newspapers, the business carried on at a railway bookstall or at a railway refreshment-room. These are the only exemptions scheduled. The Act is a short one, and its price is but a penny. It, and also the Home Office circular relating to it (price 2d.), may be had from Messrs. Eyre and Spottiswoode, the King's printers, and we advise all interested to obtain a copy of each.

MECHANICAL AIDS TO COPYING TRACINGS.

In almost any German manufacturing town can be seen displayed the sign, "Lichtpausenanstalt," denoting the business of copying the drawings, tracings, and plans used by engineers. In this country the business has never obtained this decentralisation, but is largely in the hands of a few firms who either manufacture the sensitive papers or are agents for other manufacturers' products. Many large engineering firms also have a "blue-print" or "photo-copy" department of their own, and the work of multiplying working drawings required for the workshops is done on the spot. Daylight printing was the rule for making these blue-line, black-line, and other copies, until about five years ago, when arc-light printing came into use. The common type of printer is a glass cylinder, round which the tracing is laid and the sensitive paper strapped into contact with it by an apron of stout cloth. The arc-lamp moves automatically up and down in the cylinder, and, within five minutes, fully exposes a white-line, or ferro-prussiate, copy from a tracing.

The next stage in the rapid printing of the copies is just now being reached. The cylinder printer appears to be in process of supersession by a rotary apparatus in which the longest tracing can be printed with no greater difficulty than a double elephant in the cylinder apparatus. In the first form of the machine, the tracing and sensitive paper were fed together round a large wooden drum, the sensitive paper backed against the drum, then the tracing, and then a transparent apron. On the drum rotating, the apron is wound from one roller to another, and the tracing and copy collected in a box at the base of the printer. This machine, which was patented in America by Spaulding, is said to have been used there considerably, though we have not heard of its being employed in this country.

An improved form of it, however, appears to have been worked out by Mr. J. E. Gould, the manager of the large photographic department in the Elswick works of Sir W. G. Armstrong and Co., Newcastle-on-Tyne. The "Process Year-Book," in describing the apparatus speaks of it as a "cylinder formed of glass segments, which is slowly revolved in a horizontal direction, whilst a web of the sensitive paper is fed on it, and at the same time the

tracing to be copied is fed in in contact. Powerful arc-lamps are directed on it, and the prints are fully exposed by the time the print has passed them. In this manner cyanotype prints forty inches wide can be made at the rate of 200 feet per hour, ferro-prussiate prints at the rate of 100 feet per hour, and ferro-gallic at 60 feet per hour. It would be possible to feed in large celluloid film negatives or even pieces of lace with the advantage that the whole length of a lace curtain could be printed on the paper." The machine is said to have been in use at Elswick for the past eighteen months with very satisfactory results.

A machine printer of quite a different type appears among the published patent specifications this week. In this design the tracing and sensitive paper are moved over a flat glass plate by a closely-placed series of parallel rollers, each of which, by its rotatory movement, passes the tracing and paper across the plate. The plate may be fixed in a horizontal or vertical position, and the apparatus is thus intended to serve for use by day or artificial light.

The rapidity with which any of these machines can be worked is limited by the sensitiveness of the paper. The print must be fully exposed in the time during which the paper moves across the field, illuminated whether by daylight or by arc-lamps. The various papers, ferro-prussiate, Pellet, ferro-gallic, and "sepia," vary considerably among themselves, but none of them are rapid enough to utilise the exposing capacity of a machine. At present there is no probability of more sensitive iron or chromium paper being manufactured, and, therefore, if these very rapid methods are to gain ground in copying establishments, recourse must next be had to bromide or gas-light paper. But these, we are afraid, will be too costly to make the greater rapidity of printing advisable on economical grounds. Possibly a solution of the problem might be found in the plain development papers such as were in use for solar enlarging in the days immediately before the introduction of bromide paper. Such papers are very slightly used now by enlargers, and are, of course, not commercial articles. But they possess a degree of rapidity which exceeds that of any of the iron papers, and it should be possible to coat them in roll.

THE BARNET COMPETITION, we are informed by Messrs. Elliott, was simultaneously closed in England and the Colonies on December 31, and will be adjudicated at the earliest moment. A few weeks must elapse, however, to allow time for the arrival of the Colonial portion.

In our issue for December 2 we reprinted the industrial agreement entered into by Messrs. Kerry and Co., of N.S.W., and the photographic employees. We now learn from the "Australian Photographic Review" that a meeting was held in Sydney to oppose the general adoption of the agreement, and it was resolved that a "Professional Photographers' Association" be formed and registered as an "industrial union of employers." It was stated by one of the speakers that competent employees refused to join the employees' union as they could always command good wages, and that the agreement just concluded with Messrs. Kerry and Co. would force a number of large employers into establishing workrooms in an adjacent State. As an example of the unworkableness of the conditions, he contended 15 by 12 enlargements were to cost 5s. each for artist work, when, as a matter of fact, some difficult copy enlargements could not be profitably produced under double that amount, while an enlargement from an original could be more profitably worked for 6d. It was resolved to make an appeal to all photographers in the State to join the Association, and so present a solid front to oppose this unreasonable attempt to reduce the profession to so low a level. The annual subscription was fixed at 10s. 6d. per annum.

A GREAT competition for Kodak users is announced in "The Photographer" (American), in which an invitation is made in the shape of a large "novice" class for amateurs who have never won a prize in a photographic contest. To quote the preliminary notification of the Kodak Company: "Those who have made a study of the prize lists of the various photographic competitions have been impressed with the fact that the greater proportion of the good prizes are regularly carried off by the same people. This has, of course, proved a discouragement to those of less experience. There are many amateurs who are capable of making really excellent work, yet they fall just a trifle short of that artistic excellence which has been so long cultivated in some of their co-workers. We believe that these younger enthusiasts in the photographic field are nevertheless entitled to an opportunity to carry off some of the good things in the way of prizes, and we have therefore divided this competition into two general classes, the "Open" and the "Novice," these in turn being properly subdivided. The "Open" class may be entered by any photographer (not in our employ) who complies with the conditions specified. The "Novice" class is open only to amateurs who have never won a prize in a photographic contest. While the novice classes are only open to those who have never been prize winners, the ambitious beginners may, if he is attracted by the valuable prizes and high honours offered in the open class, enter against the somewhat keener competition he will be sure to meet there. We trust that both the beginners in photography and those who have often had their names upon the honour rolls will be pleased with this eminently just and fair arrangement of the prize list. Prizes to the amount of about £400 will be offered in the competition, which will close in London on October 1, 1905.

THE RAPID RETOUCHING OF BROMIDE ENLARGEMENTS.

THE rapid and effective working-up of a bromide enlargement is an operation of considerable commercial importance. If a picture is to please, it may be artistic, but it must be effective, and not lacking in style of finish. To attain this end we may work it up entirely with the brush or air-brush. But the former is slow, and therefore not sufficiently competitive, while the latter all do not possess. Finishing in pastel or crayon has, however, the advantage of being cheap and expeditious, giving the artist great latitude and scope for display of talent, without being so laborious as brush work. Above all, it is effective, and to the public eye possesses a degree of "finish" equal to either of the other methods.

But there are different ways of doing it, and we suggest the following one as answering the usual requirements of speed and efficiency, coupled with a facility to make any alteration which may subsequently be needed.

The enlargement should be upon rough paper, mounted, and perfectly dry. If it has not been handled carelessly with the fingers, the usual preparatory rub with pumice powder is unnecessary, otherwise it may be so treated over the background and any other parts where needed except the flesh. When pumice is applied over the latter it is much more difficult to model and clean up unobtrusively.

If it is applied, well clean it off afterwards with a duster or pad of cotton wool, so that the subsequent pastel work may more readily fix itself upon the surface.

Should the subject be a vignettéd one, some powdered black pastel (Série C. Noir. No. 27," procurable from the dealers, is just the very thing) is first applied on a tuft of cotton wool over the background and more lightly over the flesh, also on parts of the accessories, as draperies, which need subduing.

A stick of soft paste should next be used, and with it the heavier shadows can be worked up bodily, softening away with stump or cotton wool as necessary, which must be accomplished so that the work does not appear to be put on, but to be an integral part of the original photograph. Bearing this latter fact in mind, and with the original before the artist for constant consultation and inspection (to ensure a perfect retention of character and likeness), a soft stump, previously charged with pastel on the pastel-pad, should then be used for modelling the hair, draperies, accessories, and, later, the features—i.e., the brows, and half tones and shadows of the flesh. Do not be afraid to work somewhat boldly, as errors can be quickly rectified by erasure, and, when the above are attended to, put in the highest lights (except the smallest and finest ones) by

applying soft velvet rubber, having, of course, regard to their correct position and nature. If the edges of these appear too harshly, soften away with a piece of cotton wool very sparsely impregnated with cuttle-fish powder. The draperies, accessories, etc., may be finished in like manner, and detail introduced where necessary.

Of course the background may be finished in any of the usual styles, as "cloud," "cloud-break," "electric," etc., the edges being softened away as described above.

"Cleaning-up" should follow, and it is surprising how little of it remains to be done, as the previous work, whilst accomplishing a different purpose, has also obliterated so many of the inequalities and imperfections. It may be done with gentle touches of an "H. H.," or No. 5 pencil (the little faint shine of the pencil marks will disappear when the picture is glazed), or with the slower brush. If the latter, then use a mixture of Indian ink and Payne's grey as the spotting medium, or Winsor and Newton's process black; Indian ink alone does not match the bromide black. Finely-pointed and extra hard black crayon in pencil form may be also used for this stage, but is far less delicate in effect.

The touch is precisely the same as when retouching a negative, only broader, and remember that when retouching bromides it is essential to sit well back from the easel in order that uneven and insignificant work may be avoided and breadth obtained.

Lastly, when everything else has been attended to (even any dirty marks in the background and elsewhere should have been previously removed with pumice and cotton wool), take a retoucher's scalpel, and, holding it at almost right angles with the surface of the paper, but really inclining a little to the left, put in the finest high-lights—on the eyes, the bridge of the nose, lace, linen, draperies, etc., using a most delicate touch so as not to abrade the gelatine film, which should not be done except in order to remove superfluous specks or copy, which work is done at the same time.

It will be seen that Chinese white, or white crayons, are not required, an advantage, as they invariably give a spoiled bluish white appearance to the parts on which they are employed.

A clever artist can easily do forty 15 by 12's in a week by the above method, providing the reproductions are from average negatives. The special features are:—(1) The work is totally devoid of hatching, which, to give an equal effect of finish, requires a much longer time for its execution, and (2) the wholesale tinting at the commencement, thus saving an immense amount of touching out of imperfections.

ARTHUR WHITING.

HALF-TONE Postcards are a special line with the London Studio Co., Limited, 20-22, St. Bride Street, E.C., who, in sending us one or two excellent specimens, state that they guarantee dispatch within four days of order.

URBANORA at the Alhambra.—A series of matinees in which the "piece de resistance" is the cinematographic display by Mr. Chas. Urban, commenced at the Alhambra on January 9. The subjects include a voyage of the Kaiser Wilhelm II. to New York and back and a series of wild beasts, birds, and reptiles from the remarkable photographs of Mr. Martin Duncan, Mr. H. M. Lomas, Mr. J. Rosenthal, and Mr. J. G. Avery. That the programme succeeds in entertaining was shown by the hearty applause with which many of the incidents were received. Mr. Urban and his colleagues deserve thanks for putting before the public an entertainment which is instructive without being dull, and is not wanting in humour.

THE Camera and Natural History.—A great many children, and

almost as many adults, spent a very pleasant time at the Alexandra Hall, Cambridge, recently, when Mr. William Farren gave a delightfully interesting lecture on "Pictures of Bird and Insect Life." The object of the lecture seemed to be to demonstrate the use of photography as an aid to natural history, and, judging from the results obtained by the lecturer, the camera triumphed. Mr. Farren was always simple and explicit, but during an hour and a half he taught his audience more than days of text books would. Birds, caterpillars, and butterflies were his chief subjects, and in each section he proved his pre-eminence as an observer and photographer. Some of his slides of herons' and owls' nests must have been secured at imminent hazard of life and limb, whilst the patience of Job must have been exercised in securing half a dozen different plates of a caterpillar changing its skin. Mr. Farren acknowledged the fascination of making collections, but thoroughly proved the superiority of the photographic methods, which were attended with no animal destruction, and could not be deprecated by any society.

THE WEEK IN HISTORY.

The British Journal in 1854.

TO-MORROW (January 14) is the fifty-first anniversary of the first issue of the "Liverpool Photographic Journal," which organ of the Liverpool Photographic Society changed its name six years later to its present title of THE BRITISH JOURNAL OF PHOTOGRAPHY. The history of the B. J. has been written, in abler language than I can command, in the special issue which celebrated its jubilee last year. Since that number was issued, one of the last links with the past has been broken by the death of Mr. James Alexander Forrest, who was one of the editing committee of the "Liverpool Photographic Journal" during the years 1854-56.

Washed Emulsion.

One of the steps towards the modern dry plate was made thirty-one years ago by W. B. Bolton, who, in THE BRITISH JOURNAL OF PHOTOGRAPHY of January 16, 1874, published the first method for preparing an emulsion with the superfluous salts washed out. An idea of the same kind had been caricatured some years before in the description of a process by which everything, from the plate-cleaning chemicals to the hyposulphite of soda, was contained in the one mixture with which the plate was coated.

In describing the making of an emulsion of pure silver bromide and "organifier," or preservative (to fill the pores with soluble matter and permit the developer more readily to permeate the film) Bolton writes:—"In the first place the emulsion is to be sensitised in the ordinary way, no particular method or formula being recommended as better than another. In this method each person may employ his own pet formula. It matters but little whether the bromide or silver be in excess—whether nitric acid or uranium be used, or both; the only requirement is an emulsion that will work. Such an emulsion having been made, it is poured on to a glass plate edged with paper so as to form a dish, and allowed to 'set,' after which it is washed thoroughly and then dried. The dried product will consist of pure silver bromide and pyroxyline (the latter having probably taken into combination a portion of the silver used in sensitising), and when redissolved in equal parts of absolute alcohol, and ether of s.g. .725 to .730, forms an emulsion containing only pure bromide of silver. In this state it may be used wet or may be washed and 'organified' in the usual way. The addition of a suitable substance, however, renders it quite independent of any 'outside' assistance, and completes what may, I think, fairly be called a 'perfect' emulsion. The preservatives I have used with success are soap and tannin, both singly and combined, the former being the more sensitive and the latter conferring greater vigour on the picture."

Collodion-Emulsion Dry Plates.

Until gelatine early in the seventies diverted experiment into another channel, the hopes of photographers were turned towards collodion emulsion for a rapid dry plate. There have been those to take a pessimistic view of that turn in the stream of progress. But it cannot be gainsaid that under the regime of collodion, photography would have remained an occupation for the adept and innocent of the great industrial developments which have followed in the track of gelatine emulsion. But there may yet be opportunities for collodion, in process work, for instance, wherefore the description of his

process communicated by Carey Lea to THE BRITISH JOURNAL OF PHOTOGRAPHY of January 17, 1868, may be included in this week's "History." "A collodion was prepared according to the formula:—

Ether	9 oz.
Alcohol	8 oz.
Bromide of calcium	128 grains.
Bromide of ammonium	32 grains.
Pyroxyline	96 grains.

This collodion should stand a month before use in order to ripen properly. It is sensitised by addition of sixteen grains of nitrate of silver per ounce. When the sensitised collodion has reposed sufficiently I decant a portion and add to it a sixty-grain solution of gallic acid in the proportion of twenty-five drops to each ounce of collodion, stirring well up. Coat the plate, previously edged with solution of india-rubber (one or two grains to the ounce of benzole), and as soon as it has set place it under the tap and wash for four or five minutes. Dry, and the plate is ready for use.

It is very sensitive, greatly more so than the ordinary run of dry processes. The negatives are clean, and the development very manageable. The process is intended either for alkaline or pyrogallic development; of course with a longer exposure in the latter case."

B. J. Sayce and Collodion Dry Plates.

It will be noticed that Carey Lea's emulsion was a bromide one, and in this it bears a strong resemblance to a formula put forward four years previously by B. J. Sayce in a letter to THE BRITISH JOURNAL OF PHOTOGRAPHY (September 23, 1864), on "Dry Plates without Washing." Sayce used tannin and wrote in reference to the addition of silver nitrate to the collodion that the idea was "very old, almost as old as collodion itself; but although the principle was in existence, to the best of my knowledge no one had ever published a method by which the idea could be resolved into a process for general use. Again, most of the experiments in this direction have been with iodised or bromo-iodised collodion, and to this do I chiefly ascribe the previous failures, for I have found by experiment that the iodide of silver will not remain suspended in the collodion sufficiently long to be of much service, and that it is not sensitive in this condition to its maximum degree, owing to the absence of free nitrate of silver."

Who Invented the Finder?

"Cherchez la France!" for the early record of accessories to the camera. The earliest record I can find of the use of a finder is a note communicated to the French Photographic Society on January 18, 1856. The author, M. Taupenot, then christened the appliance "chercheur," so that he is probably entitled to the credit of introducing a word which Germany has literally translated "sucher," but which England has turned from "seeker" into "finder." But M. Taupenot himself, if he were here, would not wish to celebrate next Wednesday as the forty-ninth anniversary of the finder. He confessed at the time that an iconometer had been designed by M. Ziegler, but I have been unable to trace the original description of the fore-runner. M. Taupenot's "chercheur" was a very simple affair, in point of fact a direct-vision finder without a lens, and he explains how it is made from an aperture or eye-hole and a frame which has its sides in the same proportion as those of the focussing screen. And he directs the mounting of eye-hole and frame so that the distance between the two can be adjusted to reproduce the view given by lenses of different focal lengths.

HISTORICUS.

THE PROGRESS MEDAL OF THE ROYAL PHOTOGRAPHIC SOCIETY.

Award to Dr. Paul Rudolph.

THE Council of the Royal Photographic Society have awarded the "Progress" medal for the year 1905 to Dr. Paul Rudolph, of Jena, "for his researches in photographic optics."

The "Progress" medal was instituted in the year 1878, and of the fifteen awards which have been made since that time one only has been granted in the domain of photographic optics, viz., that in 1896 to Mr. T. R. Dallmeyer for the tele-photographic lens. The work of Dr. Rudolph has been spread over a number of years, and has been applied to the perfection of the anastigmat lens. To appreciate its extent and continuity, we must recall to our minds the state of photographic optics at the end of the eighties.

DR. PAUL RUDOLPH, the recipient of the Royal Photographic Society's Progress Medal, 1905.

The lenses for universal use were at that time the portrait objectives proper, the landscape lenses, and the rectilinears or symmetricals. Common to all these principal systems was one great drawback. If they were spherically corrected and showed a sharp image in the centre, then there was either astigmatism or curvature of field at the margins. It was a case of Scylla and Charybdis. The optician had to put up with curvature of field if he succeeded in removing astigmatism, and he had to introduce this defect if he wanted to flatten the field. In every case where a considerable angle of view was required the flat photographic plate could not be covered with anything like even sharpness except by means of a small stop. As regards the construction of these systems, they consisted of collective crown lenses (of low refraction) and dispersive flint lenses (of high refraction), and they had as few air spaces as possible. We know now that in a

spherically-corrected objective astigmatism and curvature of field cannot be removed with these restrictions. It became possible to evade them when, in 1886, Professor Abbe and Dr. Schott, of Jena, succeeded in placing crown glasses with high refraction on the market.

The first lens to employ the new Jena glass was the Concentric of Dr. Schroeder, which, however, did not come on to the market until 1892. The Concentric was anastigmatic over a considerable angle, but its small aperture, $f/16$ to $f/32$, did not fit it for general work. The work of Dr. Rudolph has been to produce flat field anastigmatic lenses working at larger and larger apertures.

It was about this time that the proprietors of the firm Carl Zeiss, in Jena, intended to extend their manufactures, which up to this time had been almost exclusively confined to microscopes. The first step in this direction was made with photographic lenses, because Dr. Rudolph, a member of their scientific staff, had finished the computation of a new lens, for which he claimed spherical correction as well as an anastigmatically flattened field. The lens, a doublet, consisted of two collective components, formed in such a way that the positive lens in the front combination was made of ordinary crown (of low refraction), whereas in the back combination the positive lens or lenses consisted of new, highly refracting baryta crown. From 1890-1 the objectives were introduced under the designation of Anastigmat, which in 1900 was changed to Protar. As the claims were justified this type became very popular, and it has ever since been manufactured, not only by Carl Zeiss, but also by his English, French, American, and Italian licensees. The apertures of these lenses varied—as far as the most popular series were concerned—between $f/6.3$ and $f/8$, and they served as universal and wide-angle lenses.

Dr. Rudolph next directed his efforts to the astigmatic correction of the single landscape lens. He obtained freedom of spherical aberration for an aperture of $f/12.5$. These systems served as combination or casket lenses, and have been introduced as convertible anastigmats. They have become very popular, as either component of a superior doublet working at $f/7.2$ could be used as a special long focus landscape lens of high rapidity and perfect stigmatic correction.

Although great progress was realised in the new types, there was no extremely rapid objective among their number until this gap was filled by Dr. Rudolph's Planar, a system computed in 1896. This lens was essentially symmetrical, and the corrections were brought about principally by the action of eight air-surfaces. The small lenses of this series had the large aperture of $f/3.6$, and the image of a flat object was, even with this unusual aperture, flat and very sharp. These lenses have found much favour, especially for low-power micro-photographic work (up to 80 diam.).

In 1900 Dr. Rudolph brought forward the Unar, a doublet with two open components. Each combination consisted of two single lenses, including an air-space, the character of which was dispersive in the front and collective in the back component. The lens had an aperture of $f/4.5$, and it has been extensively used for hand-cameras and as a portrait lens. In 1902 the Tessar followed, a doublet with only one open component, containing an air-space of dispersive character. It has been principally used as a hand-camera lens with an aperture of $f/6.3$; but this type as well as the Planar has been further developed with the object of forming superior objectives for reproduction work. In the Apochromatic Planars and Tessars special glasses have been used in order to

remove the secondary spectrum. The achromatism of these objectives is, therefore, of a higher order, and they are specially suited for three-colour work.

Dr. Rudolph, who was born forty-four years ago at Kahla, in Thüringen, received his scientific training at the Universities of

Münich, Leipsic, and Jena. For a short time he held a tutorial position in Lauterberg, a post which he vacated in 1885 to join the staff of the Carl Zeiss at Jena. The full account of his optical work since that time would fill several issues of this journal, and we must be content with the above brief outline.

THE NEW PATENT LAW.

THE New Year saw the commencement of the operations of the Patent Act, 1902, and the following notes may make quite clear what changes are thus involved.

Investigation of Prior Patents.

The time for depositing a complete specification following the provisional application is now reduced to six months instead of nine, as it was under the old Act. When a complete specification has been deposited it is now referred to an Examiner, who, in addition to reporting whether the complete specification is substantially the same as that in the provisional, has now to institute an investigation for the purposes of ascertaining whether the invention claimed has been wholly or in part claimed or described in the complete specification of any prior English application deposited within fifty years next before the application under examination and published before the date of the latter. If the invention has been wholly or in part claimed or described in the complete specification of any prior English application the applicant is to be informed of the fact, and he may, within a given time, amend his specification, and the amended specification is investigated in like manner. The Examiner has to report the result of his investigation to the Comptroller of Patents, but it is not to be published nor be open to public inspection.

References to Previous Specifications.

If the Comptroller is satisfied that no objection exists to the specification on the ground that the invention claimed has been wholly or in part claimed or described in a previous specification, then, in accordance with Sub-section 5, he is, in the absence of any other lawful ground of objection, to accept the specification. The Act then states that "If the Comptroller is not so satisfied, he shall, after hearing the applicant, and unless the objection be removed by amending the specification to the satisfaction of the Comptroller, determine whether a reference to any, and, if so, what, prior specifications ought to be made in the specification by way of notice to the public."

If the Examiner finds that the invention claimed in the specification under examination has been wholly claimed or described in one or more specifications within the meaning of Sub-section 1 of Section 1 of the Act, he is to make to the Comptroller a provisional report to that effect, and if it be not revised or altered, this report will be deemed a final report, and the application will be dealt with as provided above.

Amendments.

Two months is the time allowed for an applicant to amend his specification. When the time allowed for amendment has expired, if the Comptroller still thinks the specification is open to objection on the ground that the invention claimed has been wholly or in part claimed or described in a previous specification, he is to inform the applicant accordingly, and appoint a time for hearing him. The applicant must notify the Comptroller whether or not he desires to be heard. After hearing the applicant, or without a hearing, if the applicant has not attended or has notified that he does not desire to be heard, the Comptroller is to determine whether reference ought to be made in the applicant's specification to any, and if so, what, prior specification or specifications, by way of notice to the public.

According to Rule 10: "When, under Sub-section 6, the Comptroller determines that a reference to a prior specification ought to be made by way of notice to the public, the form of reference shall be as follows. "and shall be inserted after the claims:—'Reference has been directed, in pursuance of Section 1, Sub-section 6, of the Patent Act, 1902, to the following specification of Letters Patent No. granted to.....' Where the reference is inserted as the result of a provisional report under Rule 7, a statement to that effect shall be added to the reference."

Contradictions.

The result of this rule will be that unless the applicant accepts the ruling of the Examiner and the Comptroller, the insertion of the above-mentioned clauses will most seriously affect the value of the patent. And in respect to this it may be pointed out that the difficulty of deciding so nice a question as to what is and what is not prior discovery is an extremely delicate task, and the insertion of such a notice seems contradictory to Section 1, Sub-section 6, which expressly provides only for a reference to prior specifications, not for a condemnatory official notification, much less one which will practically publish to the world the pith and marrow of a report, publication of which is expressly prohibited by Sub-section 4.

An applicant's specification may contain reference to prior specifications, particularly when they are very close; without necessarily casting suspicion on its validity, but the value of a patent that contains an official notification that the patent is invalid is nil.

The Examiners and the Comptrollers are not infallible, and an appeal may lie against their decision to the Law Officer, but unless he has had special training and experience in patent law, he will be no more immune from mistakes than any other judge.

A further rule provides that the statement of claim, with which a complete specification must end, shall be clear and concise, and separate and distinct from the body of the specification, and it is intimated that unnecessary multiplicity of claims or prolixity of language should be avoided.

Multiplying Patents.

Another rule which promises to press hard on the inventor is to the effect that when a specification comprises several distinct matters, although they may be applicable to or form part of an existing machine, apparatus, or process, they shall not be deemed to constitute one invention, so that the result may be that an inventor may have to take out several patents for the same thing.

Where more than one invention is included in a specification, the applicant may be allowed to amend so as to make it applicable to one invention only, and apply for separate patents for the other inventions, but it is not clear whether the original date of application would be appended to the subsidiary applications, nor whether if there is official publication of the first and amended specification, the inventor can protect the subsidiary inventions.

The Provisional Specification.

Another important point is that not only must the invention in the complete specification be the same as that in the provisional, but it is not made clear whether any amendment will be considered allow-

able that would make an amended specification claim an invention substantially different from the invention claimed in the specification as originally deposited. Thus it will be seen that many pitfalls will lie in the inventor's path, for, assuming his provisional specification, or his claims, or both, to be inadequate, he may find himself precluded from securing protection for something actually embodied in his complete specification and not anticipated by the earlier patents discovered by the Examiner.

A sealing fee of £1 must be paid on or before the last day on which a patent can be lawfully sealed.

It is further enacted that the investigations and reports shall not be held in any way to guarantee the validity of any patent.

Whilst on the whole the new Act may be considered to be an improvement on the old, there is one grave omission, and which is not an easy matter to overcome. We refer particularly to the patenting of a fact or principle, which is well known and common property; take, for example, the use of a colour filter or screen, in contact with or near the sensitive surface. This was described by Ducos du Hauron in 1867 and 1874; yet not having been patented by him it could be patented under the new Act, which would be a manifest absurdity. As a matter of fact, there is nothing to prevent any one patenting the use of the haloid salts of silver suspended in gelatine or any other colloid. The actual remedy we are not prepared to suggest, but there is an obvious danger on this point.

FOREIGN NOTES AND NEWS.

Diamidophenol Soda as a Developer.

PROFESSOR VALENTA points out in the current number of the "Photographische Korrespondenz" that Loebel's experiments on developing with the phenolates of diamidophenol and diamidoresorcine are misleading. Loebel pointed out that three molecules of caustic soda (NaOH) were required to convert the chlorhydrate of diamidophenol $C_6H_3O(NH_2HCl)_2$ into the phenolate, two molecules being required to saturate the HCl groups, and the third for the formation of the phenolate. Loebel found that such a developer gave negatives as free from fog as the ordinary sulphite and amidol developer, and that it acted three or four times as fast and gave softer results, and the following formula was given:—

Water	1,000 cc.
Anhydrous sodium sulphite...	3 grammes.
Amidol	5 grammes.
Caustic soda (1 per cent. sol.)	30 cc.

Valeuta points out that this does not form a phenolate, and that practically 300 ccs. of the soda solution must be used.

A series of experiments were carried out and plates were exposed under identical conditions in Scheiner's sensitometer, and developed at a given temperature. Loebel's corrected formula was used, and instead of a good rapid developer a deep dark blue solution resulted, which immediately fogged the plate, and precisely the same results were obtained with chemically pure preparations, thus disposing of the possibility of error through impurities. Comparative experiments proved: (1) that with the increase in the proportion of caustic soda there was within certain limits an increase in the rapidity of the developer; (2) the best result was obtained when the developer contained just enough caustic soda to saturate the HCl groups, and therefore liberated the free base. Such a developer will not keep, however, and it becomes very dark after once using; (3) the addition of as much NaOH as is requisite to saturate the two HCl groups and form the phenolate at once produces a deep blue coloration, and makes the developer unuseable.

The experiments proved that the best practical effect was obtained with an amidol developer to which only enough NaOH was added to saturate one HCl group, and such a developer is given by the following formula:—

Water	900 ccs.
Sodium sulphite crystal	10 grammes.
Amidol	5 grammes.
Caustic soda (1 per cent. sol.)	100 ccs.

This works rapidly, remains clear, and gives softer and more delicate negatives than the ordinary amidol developer.

The Setting and Swelling of Gelatine.

The work of Prof. Schroeder is briefly summarised in a recent number of "Science Abstracts," where it is stated that the viscosity, measured at 25 deg., of a gelatine solution heated at 100 deg. gradually diminishes to a constant minimum. This change is attributed to a hydrolytic process which follows a logarithmic law. Further, if after heating at 100 deg. the gelatine solution is kept at 25 deg., its viscosity increases at a rate closely related to the ability of the solution to set. With the exception only of potassium and ammonium nitrates, all the sulphates, nitrates, and chlorides of sodium, potassium, and ammonium, as well as the chlorides and sulphates of lithium and magnesium, increase the viscosity of gelatine solutions, the greatest effect being produced by magnesium salts. The order of the ions with respect to their influence on the viscosity is the same for gelatine solutions as for water. The process of hydrolysis referred to above is accelerated by both hydrogen (hydrochloric acid) and hydroxyl ions (sodium hydroxide), the final values of the viscosity thus arrived at being lower than that reached in pure or salt-containing gelatine solutions.

The Thiocarbamide Toning Bath.

Since 1902 the thiocarbamide toning bath first suggested by Hélaïn has been tested at the K. K. Lehr und Versuchsanstalt at Vienna by Herr Kessler, and he states that prints toned with it are equally as permanent as those toned by any other method, and that the consumption of gold is relatively small, and the bath is economical, as it can be completely exhausted. The bath is made up as follows:—1 g. of thiocarbamide is dissolved in 50 cm. of water, and enough of this solution is added to 25 cm. of a 1 per cent. solution of chloride of gold to dissolve the precipitate first formed, 14 or 15 cm. being necessary for this; 0.5 g. of citric acid should then be added, and the bulk made up to 1,000 cc. with water. Tartaric acid may be used instead of citric acid, and browner tones are obtained; the citric gives bluish tones. The use of nitric acid as suggested by Blake Smith gave no appreciable difference in results. The following rules should be observed in the use of this bath, which can be used for matt and glossy collodio-chloride or gelatino-chloride papers; the prints must be well washed before toning, at least three changes of water being used. Toning takes place so rapidly in a fresh bath that the prints should be immersed one by one, or at most two at a time. A bath that has been once used or is made more dilute works more slowly. Difference in temperature of the bath makes but little difference in the rate of toning. Brownish red to blue-violet tones can be obtained, and prints rich in contrasts, which frequently give double tones in the ordinary bath, do not show this trouble in this bath. Further, the bath is not poisonous.

Red Tones on Collodio-Chloride Matt Papers.

Herr Kessler points out that red and reddish brown tones on matt collodio-chloride paper are now fashionable, and states that the following bath is excellent for obtaining these:—

Prepared chalk	25 grammes.
Water...1,000 ccs.

Shake well and allow to settle, and two hours before use add to the clear supernatant liquid

Chloride of gold (1 per cent. sol.)	10 ccs.
-------------------------------------	-----	-----	---------

The bath tones slowly, and gives after two or three minutes a beautiful red-brown. The same effect can be obtained by Valenta's lead combined toning and fixing bath, but a supplementary fixing is required. The thiocarbamide bath, if diluted with an equal quantity of water, may also be used. It should be noted that after fixing, the tones with all these baths appear slightly warmer, which must not be forgotten in toning.

Stand Development with Edinol.

Dr. Englisch gives the following formula for a stand developer with edinol:—

Edinol	1 gramme.
Sodium sulphite	1 gramme.
Water	1,000 cc.

and add

Carbonate of soda or potash	...	2 grammes.
-----------------------------	-----	------------

for over-exposure, whilst for under-exposure the alkali should be increased to 5 grammes.

Exhibition.

LEWES JUNIOR PHOTOGRAPHIC SOCIETY.

THE Lewes Junior Photographic Society opened their second annual exhibition at Lewes, the Y.M.C.A. rooms being utilised for the purpose. There was a large array of pictures, especially in the classes for members only, and these showed much promise on the part of the exhibitors. The competitors had 224 pictures on view, while there were many others not for competition. Mr. A. H. Avery, of Brighton, won the first prize in the open classes with a figure study entitled "Childhood Dreams," Mr. F. Judge, of Hastings, the second, with a picture representing "A Day in August." The last-named carried off first prize for lantern slides, and Mr. A. G. Turner, of Lewes, the second. In the enlargement classes, Mr. Avery secured the first prize and Mr. A. H. C. Corder, of Brighton, the second. In the classes for members only, Mr. R. Sandals was awarded the first prize and Mr. S. Sandals the second. The judges were: Alderman G. J. Wightman (President of the Lewes Photographic Society), Mr. F. Newington, and Mr. W. E. Nicholson.

FORTHCOMING EXHIBITIONS.

January 12-14, 1905.—Boston Camera Club. Hon. Secretary, H. M. Hames, 65, West Street, Boston.

January 14-28, 1905.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

January 20-21, 1905.—South Essex Camera Club. Hon. Secretary, T. Mitchell, 180, Browning Road, Manor Road, E.

January 23-28, 1905.—Lancaster Photographic Society. Hon. Secretary, R. T. Simpson, 21, Cheapside, Lancaster.

January 28-February 12, 1905.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grand-Armée, à Marseille.

January 31-February 4, 1905.—Cardiff Windsor Amateur Photo-

graphic Society. Hon. Secretary, Mr. G. Gallon, 37, Hamilton Street, Cardiff.

February 6-11, 1905.—Blairgowrie and District Photographic Association. Hon. Secretary, Wm. D. M. Falconer, James Street Cottage, Blairgowrie.

February 16-18, 1905.—Norwich and District Photographic Society. Hon. Secretary, E. Peake, Rydal House, Earlham Road, Norwich.

February 21-March 7, 1905.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

February 24-March 4.—Northampton Photographic Society. Entries close February 7; for pictures, February 17. Hon. Secretary, E. J. Felce, 83, Adam's Avenue, Northampton.

February 25-March 4, 1905.—Birmingham Photographic Society. Hon. Secretary, Lewis Lloyd, Norwich Union Chambers, Congress Street, Birmingham.

March 4-11, 1905.—South London Photographic Society. Hon. Secretary, H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 7-14, 1905.—Brentford Photographic Society. Hon. Secretary, F. H. Read, Ferndale, Clifden Road, Brentford.

March 20-25, 1905.—The Cripplegate Photographic Society. Hon. Secretary, John B. Parnham.

March 27-April 1, 1905.—Leicester and Leicestershire Photographic Society. Entries close on March 20, 1905. Secretary, R. Warden Harvey, Oriental Cafe, Market Place, Leicester.

April, 1905.—International Exhibition, Genoa. Sec. Gen., Piazza Fontane Marose 18, Genoa.

April 3-15, 1905.—Photographic Society of Ireland. Hon. Secretary, R. Benson, 35, Molesworth Street, Dublin.

April 7-May 8, 1905.—International Artistic Exhibition, Berlin. Director, Herr Franz Goerke, Maassenstrasse 32, Berlin, W.

June, 1905.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITION.

March 31, 1905.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Limited, Ilford, E.

THE London Etching Co., 3, Holborn Place, High Holborn, London, W.C., send us some specimens of their recent work in half-tone engraving, including some striking effects in fashion drawings, done against a tint in two printings, and some high-class photo-engraved plates of portrait and architectural subjects.

PROTECTION for the hands with a film of rubber is mentioned in the following note, and should be of interest to carbon workers and others using bichromate:—"A 4, 6 or 8 per cent. solution of gutta percha in benzene or acetone when applied to the hands of the surgeon or the skin of the patient, will seal the surfaces with an insoluble impervious and practically imperceptible pellicle, which will not allow the secretions of the skin to escape, and will not admit blood, pus, or secretions into the crevices of the skin. This application has the great advantage over rubber gloves that it does not impair the sense of touch nor the pliability of the skin. After sterilising the hands and thoroughly drying them, the gutta percha solution is applied over the hands and forearms, care being taken to fill in around and beneath the nails. The hands are then kept exposed to the air, with the fingers separated, until thoroughly dry. The acetone solution dries quicker but that in benzene is said to wear longer.—Murphy, "National Druggist," abstracted in the "Pharmaceutical Journal."

New Materials.

Barnet "Tiger Tongue" Bromide Paper. Sold by Elliott and Sons, Barnet.

A new issue of this paper has appeared from Messrs. Elliott's factory with a cream instead of the white surface of the brand which we were able to review favourably some weeks ago. The two varieties are equal in price.

The "Figaro" Combination Book-Post Wrapper and Frame-Stand. Sold by Kodak, Limited, 57-61, Clerkenwell Road, London, E.C.

By providing a slip-in mount with suitable flaps at each end, the photograph is protected during transmission through the post and the flaps are afterwards turned back to serve as a support for the mount. The wrapper thus forms both a frame and a stand, and no more simple and pleasing method of presenting a single print by post can well be imagined. The mounts are in assorted designs and shapes, and are supplied for both "landscapes" and "portraits." At present they are made in postcard, quarter-plate, 5 by 4, and

certain smaller sizes, to which might be added, we would suggest, another for cabinets, which professional photographers would be glad to use as something out of the common for proofs. The wrappers are supplied in packets of eight or ten at 9d. or 1s. per packet.

Messrs. Kodak, Limited, are also issuing a lantern-slide printing-frame accommodating any size of negative from quarter to whole plate, and permitting of any portion being selected for the lantern picture. Strongly made, and with rubber-bound brass springs, the frame is sold at 1s. 9d.

ELECTROLYTIC Barium Platino-Cyanide.—A new method of preparing this salt is described in the "Zeitschrift für Electro-chemie," by A. Brochet and J. Petit, who obtain a solution of platinum in barium cyanide under the influence of alternating current. A satisfactory result is stated to be obtained from an electrolyte of 270 grammes barium cyanide, per litre, with a current of .4 ampère per square centimetre, and a P.D. of 5 volts. The product requires re-crystallising from a solution containing barium cyanide before it is fitted for fluorescent purposes in the X-ray screen.

New Books.

"Les Procédés au Collodion Bromide." By H. Calmels and L. P. Clerc. Published from the office of "Le Procédé," Paris. Price 1 fr. 50 c.

Wet collodion for the process worker is the subject of this text-book, and in its forty pages the authors manage to put the practical facts of the process as the photo-engraver has need to apply them. This they do with regard to the recent French regulation forbidding the transmission of nitrated cotton. The volume illustrates by sketches the manipulation of a plate during collodionising and sensitising. In the absence of personal instruction by a teacher, the sketches showing how to hold the plate may be commended to the student, but the knack of handling the plate is not easily acquired, and we have heard it said that no one can expect to become perfect in wet collodion who has not mastered it before he is twenty-five. MM. Calmels and Clerc also deal, as their reader would wish them to do, with the intensification of the collodion negative by lead and mercury, and the transference of it to glass supports, and to the wood engraver's block, and they append a note on the orthochromatising of the wet collodion plate.

"Deutscher Camera-Almanach." Edited by Fritz Loescher. Published by Gustav Schmidt, Berlin.

This is the first issue of a new year-book, which promises well. It contains numerous interesting and instructive articles on artistic and practical photography by well-known writers, but its chief feature is the large number of half-tone illustrations by the leading workers on the Continent.

A BURGLARY was committed during the night of Monday, January 2nd, on the premises of the Photographic Supply Stores, a lock-up shop at 24, Widmore Road, Bromley.

THE death took place on Saturday, at his residence near Wrexham, of Mr. Edward Evans, for many years head of the great firm of manufacturing chemists in Liverpool. Mr. Evans, who was in his eighty-eighth year, retired from active business only two years ago, after which the firm was amalgamated with the London house of Evans, Leecher, and Webb. Mr. Evans was one of the original members of the Pharmaceutical Society.

RECENT Lantern Slides.—The latest list of Messrs. Newton and Co., 3, Fleet Street, London, E.C., describes the 158 subjects of the Russo-Japanese war, which are now ready as lantern-slides. There are also further series of slides showing the Trans-Siberian Railway (from direct negatives), Japan, as photographed by Dr. Vaughan Cornish, and the Evolution of an Ironclad. Messrs. Newton issue slides from the copyright pictures in the illustrated weeklies, and the list of these subjects, which deal only with current events, now numbers 245. The list is sent free.

DR. DOYEN, the famous Parisian surgeon, has brought an action against the firm which has for years kinematographed his more important surgical operations. Dr. Doyen's idea was to leave a record of his particular system of operating, and to utilise the films for lecture purposes. The firm in question, however, have distributed positives all over Europe and America, and even shown them at country fairs, and it is even stated that a Parisian hostess, anxious to provide her guests with a novel entertainment arranged an exhibition of some of the films after a dinner party. The sale and exhibition of these films have been against Dr. Doyen's wish, but being unable to stop the same he has now claimed 200,000 francs as damages. Judgment in the case has been reserved.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MEETING held January 5, 1905; Mr. Brigginsshaw presiding.—Mr. Freshwater announced that Mr. Phiup Everitt, formerly Honorary Secretary, was lying ill at Guy's Hospital suffering from tumour on the brain, which it was hoped could be dispersed. The Chairman was sorry, and voiced the hope of the members that Mr. Everitt would speedily recover.

Mr. Wardell exhibited a new focal-plane camera by Zeiss, which had many excellent points of novelty. Mr. Wardell's lecture on "A Large Aperture," resolved itself into a talk on the optical properties of the new Jena glass, as contrasted with the old crown and flint. This was very ably given, and was listened to with great attention, but it occupied the time allowance, and left no opportunity of informing the members how lenses of large aperture should be used. Mr. Thomas, as a user of lenses of large apertures, would have been glad of some hints as to the use of lenses working at $f4$ with a focussing scale, as, unless it was known that that scale was accurate, and the judgment of distance correct, the results were disappointing, and he had no doubt but what such lenses were best used in a reflecting camera, enabling the operator to focus up to moment of exposure.

ROYAL PHOTOGRAPHIC SOCIETY.

JANUARY 9.—Major-General Waterhouse in the chair.—Scrutineers of the ballot for the election of officers were elected, and the award of the Progress Medal to Dr. Paul Rudolph, of Jena, "for his researches in photographic optics," was announced. Mr. T. Thorne Baker read a paper on "Spectroscopic Photography in Colours," in the

course of which he spoke in favour of the diffraction spectrum as the most suitable means of adjusting plates and filters, and said it was convenient to make five exposures on a quarter-plate; two to the entire spectrum and the remaining three separately through the three filters. In considering sensitive materials, he divided panchromatic plates into two classes, those with three maxima and those with an even band of sensitiveness. Bathed plates were superior to colour sensitised emulsions, and the most perfect sensitiser in his experience was Homocol, which gave sensibility into the infra red. The absorptions of the filters should not end abruptly, but diminish gradually, so that rays of adjacent parts of the spectrum were passed in diminishing proportion. If these conditions were satisfied, proper exposure of the three plates would give a perfect set of negatives, but it often happened that the negative of the yellow printer was under-exposed, and green and red negatives over-exposed. A three-colour reproduction of the spectrum of incandescent gaslight was shown from blocks prepared with only the treatment that any ordinary half-tone block would receive; no re-etching was given for false colour rendering.

The following are, in round numbers, the constituents of the filters:—

Blue.	
Methyl blue	10 parts.
Naphthol green	1 part.
Green.	
Patent blue	25 parts.
Naphthol green	26 parts.
Tartrazin	31 parts.
Red.	
Tartrazin	70 parts.
Titan scarlet	22 parts.

The gas was placed about one foot away from the slit of the spectroscopic camera, and the exposures, 1-1 plate, were found to be for the blue record one minute, for the green record three minutes, and for the red record seven minutes.

The annual meeting of the Royal Photographic Society will take place on February 14, when the election of Council officers and judges will be announced, and the balance-sheet presented. Nomination papers are now in the hands of members, and must reach the Secretary not later than January 20. The members of the present Council and their attendances at meetings are as follows (the figures in parentheses after each name gives the number of possible attendances):—Sir W. de W. Abney (12), 5; The Earl of Crawford (12), —; Thomas R. Dallmeyer (12), 3; Major-General J. Waterhouse (12), 11; Sir H. Trueman Wood (12), 1; John Sterry (12), 9; Francis Ince (12), —; T. Bedding (9), 2; H. W. Bennett (9), 7; James Cadett (12), 2; St. Lawrence Carson (12), 3; Leslie E. Clift (11), 10; Douglas English (12), 6; T. E. Freshwater (12), 9; C. F. Grindrod (9), —; A. Haddon (12), 7; John A. Hodges (9), 6; G. Lindsay Johnson (12), 6; Rev. F. C. Lambert, M.A. (9), 5; J. C. S. Mummery (12), 10; C. H. Oakden (12), 10; E. Sanger Shepherd (12), 7; Sir Joseph W. Swan (12), —; John Spiller (9), 7; Prof. W. C. Unwin (12), —; H. Snowden Ward (9), 8; B. Gay Wilkinson (12), 8.

SOUTHAMPTON CAMERA CLUB.

THE members of the above club assembled in goodly numbers on Monday evening, the 9th inst., at the club rooms, for the lecture by Mr. A. J. Kay, M.I.N.A., of Glasgow, on "Strathearn," and although Mr. Kay was unable to make the journey owing to press of business engagements, his brother, Mr. W. R. Kay, of the Southampton Club, was able to do full justice to the very excellent description by his brother of their home neighbourhood. The lecture proved to

be a summary of the delights of a two days' walking tour through the "strath" or plain through which the river Earn flows, and the lecturer demonstrated that within easy reach of murky and commercial Glasgow could be found such a wealth of beauty in river, wood, and hill as might satisfy the most exacting tourist. The slides were, technically, of the finest quality. A very hearty vote of thanks to the lecturer and the reader was accorded at the instance of Mr. G. Vials, who, on presiding for the first time after his election as vice president of the club, was given a most cordial reception.

CROYDON CAMERA CLUB.

JANUARY 4.—"The Face and Figure of Woman," considered respectively from the painters' and photographers' point of view, formed the somewhat startling title of an unconventional and carefully thought out lecture by Mr. P. R. Salmon, the Editor of the "Photographic News," an ever-welcome visitor at Croydon. In less skilful hands the subject—illustrated, as it was, by copious illustrations of the nude—might readily have become offensive, and Mr. Salmon is to be congratulated in having presented it in such a way that no objection, even from the most straight-laced, could reasonably have been taken. The lecture, of which little more than an epitome can be given, aimed at, and very convincingly succeeded in, drawing a sharp comparison between the idealisation of the artist and the realism of the camera, strive its operator ever so hard and so cleverly to make the best of things as he finds them.

First came slides representing well-known paintings, followed by the lecturer's own studies of the living model, these frequently being favourite professional sitters to the painters, whose idealistic interpretations were also shown. Occasionally the models were posed in exact imitation of the original picture. Judged purely as examples of technical excellence, happiness in lighting and pose, Mr. Salmon's studies left little to be desired. But considering them as competing with the artist's work, then the camera broke down so completely that even its most enthusiastic pictorial exponent must have been compelled to recognise so patent a fact. To the artist, or art student, Mr. Salmon merely emphasised a settled conviction, whether right or wrong. To others, there can be but little doubt, he taught a valuable lesson, albeit the familiar cheerful prattle of "leading in lines," "pyramidal," and other forms of composition, "concentration of interest," and so forth, were never even touched upon.

Dealing with the first part of his subject, Mr. Salmon discussed, and controverted, the popular impression that actresses, as a rule, were better looking than the average girl. Personally, he much preferred to photograph a natural face than a made-up one, however alluring the latter might be behind the glitter of the footlights. Notwithstanding this, prominent actresses demanded, and succeeded in obtaining, enormous fees for sittings, the much-maligned retoucher making good all deficiencies. As a matter of fact, pretty photographic sitters, drawn from any source, were extremely difficult to get, and the regular models were expensive—as he knew to his cost. There was one thing, he said, a photographer, unlike a painter, could not do, namely, idealise a type and popularise it. Thus, for instance, in the fifteenth century in Italy there was the "Botticelli girl," just as in the present day there exists in America the "Gibson girl." Greuze, Reynolds, Gainsborough, Rossetti, Burne-Jones, Tenniel, Du Maurier, and many others also created types, and no doubt the artist's preference for one living woman was mainly responsible for this. Mr. Salmon was evidently not lost in admiration of the buxom types of Venus, Diana, and the like, evolved by Rubens; but in justice to this master he might have pointed out the magnificent flesh rendering his paintings always show. Beauty, he went on to say, no doubt was the caprice of fashion, but,

in any case, it might be classified under four headings:—Colour, form and expression, grace. The first two being, as it were, the "body," and the two last the "soul."

Turning to the photographic attempts to portray the nude, these, he said, were many, but the successes few. It was, in fact, one of those subjects in which photography signally failed because of its truthfulness. On the other hand, the foremost painters disregarded the canons of science, as a careful measurement of their pictures would show; but "science was not art." The human figure in the nude very rarely lent itself to photography owing to its imperfections. One model might have a perfect throat, another exquisite arms, a third glorious shoulders or a "Tribby" foot, but seldom, if ever, was such a combination found in one figure. An artist, taking the best points of each model, could obtain a combination of perfections almost impossible of attainment by the photographer. There was, as he very truly said, a wide gulf between the naked and the nude. It was the naked, and not the nude, which the camera generally gave. There was, in fact, too much realism. The nude belonged to the poetic art, and was the divine ideal; it had no excuse for existence if not beautiful, and the modern nude was not beautiful.

From the foregoing abbreviated utterances of Mr. Salmon it might be thought he despaired of any photographic representation—considered as a work of art—of the modern woman, unadorned, or unencumbered with the complex trappings of civilisation; but this was not altogether the case, and if his concluding remarks appeared slightly at variance with what had gone before, this doubtless was due to a not unnatural desire to regard the matter free from prejudice, and with hope for what the future might bring forth. Speaking of the semi-nude, or partially-draped studies, he said he had seen photographs "which were as artistic as any painting could possibly be." He had also an idea that photographs of the nude, properly treated and properly painted, might be made into pictures "real pictures," which no one need be ashamed of hanging up in a drawing-room. In this connection we are regretfully bound to record that beyond a recommendation that such photographs should be printed on rough paper, Mr. Salmon gave no further indications how they would be made into "real pictures," a term, which with the word "artistic" previously used, involves a certain amount of ambiguity, and claiming much or little according to the varying interpretations which might reasonably be put upon them; but, be this as it may, there was certainly no indefiniteness in the hearty vote of thanks, accorded to the lecturer for a most interesting and pleasant evening, which terminated with an animated discussion.

SUTTON PHOTOGRAPHIC CLUB

PHOTOGRAPHY with chromium formed the subject of an interesting paper which Mr. Hector Maclean read at the above club on January 5, and which was introductory to a demonstration of the new and promising printing process known as "auto-pastel," a method of making photographs which have many of the qualities of "gum prints." The lecturer explained that the paper was procurable ready coated in eight tints, that it was easily sensitised in one minute, and might be dried and ready for printing half an hour afterwards. He also demonstrated how by means of a dish of hot water and a soft brush any one can develop the paper, which, unlike carbon, requires no squeegeeing or stripping. In the course of his remarks upon chromium and its services to photography, he stated that, apart from negative making, the world could better sacrifice the photographic properties of the salts of silver, gold, platinum, and iron rather than those of chromium, on account of the utility of the last-named in the carbon, gum, collotype, and photo-mechanical processes.

A number of striking prints were shown, including choice specimens reproducing pictures by Degas on "Papier Fresson," by Mrs.

Coles, a selection of Mr. Rawlins's most recent "oil prints," "auto-types," gum-bichromate prints by Messrs. Chas. Moss, F. A. Bolton, and by the lecturer; "auto-pastels" in variety, and collotypes, including unique examples on white satin kindly lent by the Auto-type Co.

WAKEFIELD PHOTOGRAPHIC SOCIETY.

At the Church Institution on January 6 Mr. F. W. Plews, of Leeds, gave a practical demonstration on "Dry-plate Making." He reviewed the conditions which now obtain with dry-plates as compared with the past, when only the wet-plate process was available. The new conditions were the result of experiments by Dr. Maddox, a Liverpool amateur photographer. Mr. Plews described all the formulæ and appliances necessary, and also proceeded to make up the solutions and coat the plates with plain and stained emulsions.

ILLUSTRATED directions for the use of the "Crossed Swords" gum-pigment paper reach us from Messrs. Chas. Zimmermann and Co., 9-10, St. Mary-at-Hill, London, E.C.

THE Optical Lantern.—"The Camera House Journal" of Messrs. Butcher and Sons refers, in its current issue, to certain articles on the "Revival of the Optical Lantern," among which is doubtless included that in the BRITISH JOURNAL OF PHOTOGRAPHY for September 16, 1904. On the factors concerned in reinstating the lantern in favour, the "Camera House Journal" writes: "There are two things that may have caused the popular interest in lanterns to wane, one is the abomination known as a three or four-wick lamp, and the other, the flood of rubbishy slides that have been, and continue to be, offered for hiring purposes. It is right enough to endeavour to popularise a trade by cheapening it, but it is quite possible to overdo it, and when dealers commenced to hire out slides at 6d. per dozen, all slides at one price, they overlooked the fact that some slides are worth more than others, and it was absurd on the face of it to hire out slides that cost 30s. for the same rate as others that cost only 10s. The consequences soon became apparent; they naturally, as business men, only put into stock those slides that could be bought cheapest, and the better class and quality became conspicuous by their absence, and are now not readily obtainable at all. It is not too late for dealers to try and redeem the position. They should re-arrange their hiring terms on a sounder basis, and have at least two scales or even three. Those sets of slides which have been kept in stock for years can still be hired out at the 6d. rate, but the new sets should be put up to 9d. or 1s. There would then be a paying margin and an incentive to purchase better quality slides and especially better coloured ones. There is no overlooking the fact that all animals are more attracted by coloured pictures than they are by monochromes, and the human animal is quite as susceptible as are butterflies and birds, it is therefore, only reasonable to understand that coloured lantern slides are more popular than plain ones, but they must not be daubs. As regards oil lamps, until three or four years since they were the only means of illumination for a lantern show on a small scale or at home, with the exception of acetylene generators. They were portable and inexpensive, and almost anyone could light up a lamp after a style, but the light is poor in quality, and the greater part of the lamp's energy is dissipated in smoke and heat. There are now on the market two very excellent "spirit lamps," which are quite as portable, as inexpensive to use, and as easy to operate as any oil lamp, but they give a much more brilliant light. There is no smoke or smell whatever, and comparatively little heat. If the lantern is to revive in earnest for home use these spirit lamps will play no small part in effecting the revival. When once they are fully understood it is really remarkable the amount and quality of light they give, and how easy it is to maintain."

Photo-Mechanical Notes.

The Dry Plate in Process Work.

THE time taken to finish and dry a gelatine plate is extremely irritating to the operator who is accustomed to wet collodion. He soaks the plate in methylated spirit to hasten the drying after what he considers a prolonged washing, and then finds his labour in vain because the film becomes quite opaque with a yellow opalescence when he takes it out of the spirit and it begins to dry. This is due to the fact that the hypo has not been properly washed out. A very short washing now will remove the opalescence and then the plate may be replaced in the spirit without fear. But, of course, no one wants to go this roundabout way to get rid of the hypo, nor does one want to wait for sufficiently prolonged washing in the first place, for in process establishments it is often of the gravest importance to save every minute.

Now, plates can be quickly dried with very simple precautions. First the plate should be thoroughly fixed, cleared of silver in one hypo bath, and then transferred for a minute or two to a clean 20 per cent. bath of hypo. Then a minute under the tap, and place the negative in a shallow dish of water and add a few drops of a solution of permanganate of potash just sufficient to turn the water pink. The colour will at once be discharged, the water is then poured away, fresh is taken, more permanganate added, and the operation repeated until the colour of the water remains pink; which is an indication that all the hypo is gone. This is one of the simplest and cheapest of Lyco eliminators and thoroughly satisfactory. It is perfectly possible to safely place a negative in spirit within three minutes of taking from the hypo if this method is used. Wipe off superfluous moisture with a pledget of cotton wool, and allow to remain for two minutes in the spirit. Then take out and replace in another bath of spirit—not previously used—and after two minutes in this, the negative can be removed, wiped over with another piece of cotton wool, and it will be ready within a few seconds, especially if slightly warmed. The methylated spirit after use should be renovated by shaking up with dried potassium carbonate and then decanting or siphoning off the spirit from the top.

Since density is nearly always required in process work, hydrokinone is the best developer to use, and to save time in this operation, the formula can be made up much stronger than that usually recommended by the plate makers. For example, a good formula is as follows and will be found in every way satisfactory for any plate likely to be used for photo-mechanical work:—

A.			B.		
Hydrokinone	... 1 part	...	Caustic potash	...	
Metabisulphite of	sticks	...	2 parts
potash	... 1 part	...	Water	...	40 parts
Potass. bromide	. 1 part				
Distilled water	... 40 parts				

Take equal parts A and B.

Orthochromatic Wet Collodion.

Wet collodion, which would be of much greater service to the process worker were it possible to work it readily in a colour-sensitised state, has received but scant attention from the investigators who have recently been at work on the newer methods of orthochromatism.

Formulae for orthochromatic wet collodion plates are few and far between, and operators who have used them rarer still. Some directions which MM. Calmels and Clerc append to their text-book on wet collodion are as follows:—

COLLODION.

Alcohol pure 96 per cent.	100 cc.
Cadmium bromide	20 gm.
50 per cent. solution of eosin in alcohol, 96 per cent. ...	25 cc.
Alcohol, 96 per cent.	300 cc.
Ether, 65 degrees	525 cc.
Nitrated cotton, H.T.	14 gm.

or

Ether, 65 degrees... ..	175 cc.
Twenty per cent. collodion	700 cc.

The plate is edged with rubber solution before the collodion is flowed on, with the object of preventing the lifting of the film in the considerably acid sensitising bath.

SENSITISING BATH.

Distilled water to make	1,000 cc.
Silver nitrate	150 gm.
Alcohol	70 cc.
Acetic acid	A few drops.

The plate is immersed until all greasy markings disappear. After exposure and before development it is placed for three minutes in the following bath:—

Distilled water, to make	1,000 cc.
Silver nitrate	12 gm.
Nitric acid	A few drops

so that the plate may reach the developer containing nitric acid in the pores of the collodion. In default of this, the image is grey and fogged. The other operations, fixing, intensification, etc., are done as usual.

Lenses for Process.

The requirements of the operator in half-tone and three-colour are the subject of some notes by Fritz Hansen in "Photographische Kunst." Though the cautions he lays down are not new, it is well to bear in mind the great need of flatness of field in a lens for process and the absence of spherical aberration at the working aperture. As regards these and the equally important property of proper achromatism, reference is made to the Apochromatic Collinear of Voigtlander, the Apochromatic Tessar and Planar of Zeiss, and to a new lens, the "Alethar" of Goerz, which is spoken of as an excellent instrument for process.

Chalks for Half-Tone Etching.

A soft fatty chalk, which only requires warming for application to the half-tone plate instead of the subsequent dusting with resin powder, consists of:—

Venetian turpentine	10 parts.
Yellow wax	30 parts.
White dry soap	20 parts.
Talc	10 parts.
Nitric acid, 1:10	10 parts.
Fine lamp black	1 part.
Graphite (Siberian)	5 parts.

In giving this formula in the "Photographische Chronik," Herr C. Fleck directs its preparation as follows:—The wax, talc, and turpentine are mixed in a deep, air-tight covered vessel such as an autoclave, of size such that it is only half-filled by these constituents. The soap is then added in fine shavings, and the whole raised to boiling. The heated mass is then removed from the fire, and ignited with a taper, being allowed to burn for about one and a half to two minutes. The cover is then put on to extinguish the flame, removed for a

moment and the nitric acid dropped in from a pipette, whilst the mass is vigorously stirred by an assistant. The mixture is then again heated, again ignited and allowed to burn for from one-half to three-quarters of a minute. After again extinguishing the flame, the graphite and lamp black, made into a paste with a little spirit and a few drops of glycerine, are stirred in. A stone plate with an edging of lead is prepared by rubbing its surface with poppy oil, and the fluid mixture poured on to it, being cut up into convenient sizes when the mass has hardened. The chalk must be protected from frost and damp.

Fac. Sim. Reproduction of Pencil Drawings.

A revised form of what is commonly spoken of as the "high-light" process is given in "Zeitschrift für Reproduktionstechnik" on the recommendation of Otto Mente, of the Klimsch Process School in Frankfort. It is based on the formation of images of the stop by suitably choosing the screen distance, the shape of the stop being similar to that of the screen opening as shown in the figure where the shaded squares are the apertures of the screen. With screen and stop thus adjusted, the adjacent dots join up completely in the negative, and thus the ground of a pencil drawing can be rendered quite opaque, whilst the lines are more or less broken. The *modus operandi* will be somewhat as follows: An exposure is made on the drawing with a comparatively small stop, and the square stop, figured above, then inserted to close up the ground. This

Fig 1

latter stop is turned round in the lens so that two of its sides are exactly parallel with the lamination of the screen. The square stop should be not larger than is necessary to effect the closure of the dots, for over-lapping may lead to the dots of the drawing becoming too light, and some fine detail may be lost. And this may occur also if a stop of the right size is exposed too long. Stop and exposure must be correctly adjusted to sharply mark out the drawing from the ground without vignetting. The negative is developed and fixed and intensified with copper bromide and silver nitrate. More powerful intensifiers, such as lead, should not be used, as the reproduction of the drawing suffers. The process saves an immense amount of tone and hand-work, which such subjects require at the hands of the fine-etcher and router.

Circular Screens for Three-colour Work.

The advantages offered by a screen of circular form have stimulated the efforts to minimise the disadvantages which have been found to attend this form of screen. Only two objections have been urged against the circular screen (writes Max Levy in "The American Annual of Photography"); one, the difficulty of turning in the holder or

camera, which is purely mechanical and can readily be overcome, and when overcome in the manner shown below, affords a further advantage over any other existing method in the complete protection of the screen from the silver solution and the large measure of further protection from accidental injury through jar or other causes. I have recently designed an arrangement and constructed a lathe for turning the aluminium rings up to 72 inches in diameter. In this arrangement the screen is carefully fitted and cemented into a ring turned from an aluminium casting, and this ring is arranged to rotate upon two friction rollers and a friction clamp, all of which are mounted upon a framework carefully built up of sheet aluminium and properly braced. The ring is graduated half way around, the gradations being fifteen degrees apart, and a pointer is mounted upon the framework by which the angle is read off. The direction of the rulings is carefully marked upon the screen, and one of these rulings is made to conform to 0 degrees and 180 degrees on the circular frame. A screen 40 inches in diameter, made for my exhibit at the Louisiana Purchase Exposition (St. Louis, 1904), is mounted in this manner, and moves with the greatest possible freedom and precision, so that in using such a screen there need be no fear whatever of any error in the angle of the rulings in resulting plates.

The chief obstacle in the way of the use of the circular screen is the extra large size of camera and plate holder required. The effect of this disadvantage is reduced by placing the screen in the camera instead of in the holder, the former being the English and Continental, the latter the American practice. I am able to say at this time that the difficulty is substantially, if not entirely, removed by an ingenious contrivance I have seen, in which a plate holder of the normal size for the required plate is employed in connection with a circular screen and framework considerably larger, the screen and framework being mounted in the back of the camera, with ample provision for cleaning the screen without removing it from the camera. I am unable to give full particulars of this device, as the inventor is not yet ready for publication.

Grain Versus Cross-line Screen.

The paper by Mr. Max Levy, before the Royal Photographic Society, and reported in our issue of December 30th last, appears in full in the December issue of "The Photographic Journal." On Grain Screens Mr. Levy says: "An irregular grain means, that of the elements of black and white which form the resulting picture, some are large and some are small, and that they are irregular in form and arrangement. If it were possible to attain such a result, and at the same time have the character, direction, and size of the elements varying in conformity with the character or texture of the subject, the result would unquestionably meet the highest ideals, but such a thing is entirely out of the question. It may be set down as an unquestionable fact that a picture having no visible texture is better than one with any texture that can be conceived of as possible of attainment. The uniformly ruled screen of 175 lines to 200 lines per inch produces a surface which has, to all intents and purposes, no visible texture. If an irregular sub-division is to be had that shall be equally unobtrusive, its smallest sub-division must be at least as small as the elements of the screen with which it is compared. It must also have an irregular surface for printing—that is, a surface in which some of the elements are larger and some smaller, and in which none exceeds the single elements on a 175 or 200 line screen. This would make a printing plate which could certainly not be used in the present state of the art. I therefore long ago came to the conclusion that no irregular grain surface can be produced which will hold its own with a cross-line screen of suitable texture in rendering all classes of subjects, and I am confident that time and experience will confirm this determination."

Major-General Waterhouse "thought Mr. Levy was right. It was exceedingly difficult to get an irregular grain which would produce

proper gradation and relief in the image, and it was impossible to regulate the diffraction effect as was quite feasible with cross-lined screens. The image was either too much broken up, and rough or spotty, or was covered with an even tint in the lights which was ruinous to effect. The best results of this kind could perhaps be obtained by a reversal of the ordinary photogravure process so as to produce a relief block with a fine dust grain."

At a recent meeting of the Photographic Society of Vienna, the Graphische Gesellschaft "Unie," of Prague, exhibited two colour prints in orthotype, which was stated to be a photographic half-tone method, based upon the light sensitiveness of asphalt, and which was applicable for one or more printings without the use of a ruled screen.

The death is announced of William Kurtz, at Rockaway, U.S.A., aged 71. He was born in Frankfort-am-Main, Germany, but went to America about twenty years ago. He was instrumental in introducing the Kurz-Vogel method of trichromatic printing into the States, and his company also produced fine half-tone and photogravure work.

Application for Patent.

No. 28,592. "Improvements in the methods of printing from photo-engraved intaglio plates." Sir Joseph Wilson. Swan and Donald Cameron-Swan, 116, Charing Cross Road, London.

Patent News.

The following applications for patents were made between December 27-31, 1904:—

DEVELOPMENT CAMERA.—No. 28,521. "An improved photographic magazine camera and developing box combined. Thomas Henry Vickers, 14, Egremont Place, Brighton.

COLOUR PHOTOGRAPHY.—No. 28,544. "An improved process of producing and fixing photographic portraits in natural colours." Alfred Cleaver, 10, Richmond Terrace, East Twickenham, Middlesex.

DEVELOPING FILMS.—28,594. "Improvements in means of developing photographic films." Henry Harris Lake, 7, Southampton Buildings, Chancery Lane, London (Charles Harris Shaw, United States).

PRINTING BORDERS.—No. 28,594. "Improvements in and relating to masks for printing, borders around the edges of sensitised picture-postcards, photos, and the like." Harold King Smith, 322, High Holborn, London.

FILMS.—No. 28,863. "Improvements in means for carrying and exposing in the camera photographic plates or films." Robert Ballantine and Matthew Ballantine, 37, West Nile Street, Glasgow.

PLATE ENVELOPES.—No. 28,869. "Improvements in protective coverings or envelopes for holding photographic plates or films." Frederick Mackenzie, 65, Chancery Lane, London.

FLASHLIGHT.—No. 28,919. "Flashlight apparatus for use in photographic operations and the like." Frederick Fitz Payne, 27, Chancery Lane, London.

RAY DIFFUSER.—No. 28,984. "A new ray-diffusing device and apparatus for use in photographing objects." George Hughes, 22, Fumival Street, Holborn, London.

CINEMATOGRAPH.—No. 29,051. "An improved cinematographic process and mechanisms for effecting same." Robert Thorn Haines, 322, High Holborn, London.

DEVELOPMENT APPARATUS.—No. 29,388. "Improvements in stand developing, fixing, and washing photographic apparatus." William Frederic Butcher, 322, High Holborn, London.

HAND CAMERAS.—No. 29,389. "Improvements in 'infinity' catches for photographic cameras." William Frederic Butcher, 322, High Holborn, London.

PHOTOGRAPHING TELEGRAPHS.—No. 29,428. "Improvements in automatic photographing telegraphs." Paul Ribbe, 323, High Holborn, London.

LENSES.—No. 29,561. "A method of increasing the brilliancy of the images formed by lenses." Harold Dennis Taylor, Buckingham Works, York.

LENSES.—No. 29,562. "Improvements in photographic and other lenses." Harold Dennis Taylor, Buckingham Works, York.

EXPOSING PLATES.—No. 29,587. "Improvements in and relating to means for packing, carrying, and exposing in the camera photographic dry plates or films." Frederick Mackenzie and George Wishart, 17, Douglas Street, Glasgow.

FOCAL PLANE SHUTTERS.—No. 29,656. "Improvements in focal plane shutters for cameras." Robert Ballantine and Matthew Ballantine, 37, West Nile Street, Glasgow.

Some Recent French Patents.

COLOURING SILVER PICTURES.—No. 345,033. See "Ex Cathedra." O. Gros.

SENSITIVE COATING FOR PHOTOGRAPHIC PAPER.—No. 345,206. "Paper coated with gelatine and zinc oxide is sensitised in silver nitrate or citrate. Prints of pleasing black tone are produced. They require no toning, but are simply fixed in hypo. The paper may be slightly exposed and the image developed." George Hauser.

STRIPPING FILMS.—No. 345,535. "A gelatine film, from 8 to 10 m.m. thick, is backed with collodion and a coating of gelatine emulsion applied to the unbacked side, the collodionised surface being fixed to a temporary support with an albuminous adhesive, soluble in water." M. Bry and Co.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 3d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

COPYING TRACINGS.—No. 3,382, 1904. "A machine for making photo-copies of tracings and drawings of any length. It consists of a flat glass plate, fixed in a frame, against which presses a series of rubber-covered rollers, which feed the tracing and sensitive paper between themselves and the plate. This is done at an adjustable pressure and at an adjustable speed, so that the printer can be suited to the sensitiveness of the paper. Small tracings can be fed through in the same way one after the other without altering the apparatus." H. R. Watts, Arrandale, Arran Avenue, Brooklands.

PRINTING FRAMES.—No. 3,648, 1904. "A printing frame designed to prevent the paper shifting (on examination) and the negative from being scratched when the paper is lifted off. In accomplishing the first of these ends one part, the smaller, of the hinged back is clamped to the end of the frame by a nut and bolt arrangement, the end of the frame being slotted for this purpose, or other devices used to clamp the back. To lift the paper slightly when the free back of the frame is opened a light spring plate is attached to the outer frame, overlapping the rebate on which the negative rests. The spring being permanently sprung upward, the paper is raised sufficiently to enable the operator to lift the same without damage to the negative." H. J. Spratt, A. S. Spratt, and G. A. Spratt, Tudor Works, Hackney, N.E.

OPTICAL PROJECTION APPARATUS.—No. 20,967, 1904. "Construction to admit of the automatic focussing of each slide as it is brought opposite the objective, the apparatus being of the type in which a series of slides are mounted on a carrier which is intermittently actuated by automatic means." G. C. Marks, 18, Southampton Buildings, Chancery Lane, W.C. (communicated by J. W. Mead and H. A. Mackie, of Amsterdam, New York State, U.S.A.).

Commercial & Legal Intelligence

For attempting to defraud the revenue by posting letters bearing cancelled stamps, a photographer named Speed was fined £25 and £8 costs at Colchester Police Court. In default of payment he went to prison for three months.

FOULSHAM and Banfield, Limited (82,984).—Registered December 22. Capital, £1,000 in £1 shares. Object, to carry on the business of photographers, photographic printers, photo-lithographers, printers, stationers, manufacturers of and dealers in negatives and pictures, etc., and to acquire the business carried on by Foulsham and Banfield at 95, Wigmore Street, W. No initial public issue. The first directors are R. Baelz and E. Cruesemann.

PICTORIAL Postcard Company, Ltd.—The above-named company has been registered with a capital of £2,000 in £1 shares. Object: to acquire the business carried on by Alice M. Honnest, of 15, Red Lion Square, W.C., as the Pictorial Postcard Company, and to carry on the business of picture postcard manufacturers and dealers, stationers, photographers, printers, etc. No initial public issue. Registered without articles of association.

EMPIRE Bioscope Company, Ltd.—The above-named company has been registered with a capital of £1,000 in £1 shares. Object: to carry on the business of public entertainers, to manufacture and deal in photographic apparatus, lanterns, lamps, films, cameras, and other instruments and accessories for animated photography or otherwise, makers of gramophones and phonographs, etc. No initial public issue. Registered without articles of association. Registered office, Cecil Chambers, 86, Strand, W.C.

COPYRIGHT of a Photograph.—At the magistrate's court, Wellington, N.Z., judgment for £60 was given for plaintiff in the case, *Tomlinson v. Hardy Shaw and Henry Clark*, claim £95 damages for the infringement of a copyright of a photograph of the New Zealand representative football team. The plaintiff registered the copyright, and obtained a certificate on August 15. Plaintiff wished to sell reproductions, and got a process block made by the defendant Shaw. The plaintiff then proceeded to get postcards containing reproductions printed. Certain other parties reproduced in certain football programmes defendants' photograph, with some obliterations. The process block for this reproduction was admitted to have been made by defendant Clark, who is in the employ of the defendant Shaw. The issue of the New Zealand team on these programmes materially interfered with the sale of plaintiff's postcards. It was alleged that Clark had made the block contrary to the instructions of his employer. The latter, however, was responsible for Clark's action.

CINEMATOGRAPH Accident.—A somewhat alarming incident occurred towards the close of a performance at the Southport Pier Pavilion. A cinematograph entertainment was being given, when the films suddenly caught fire. There was at once a rush for the door by some of the audience. The attendants, however, quickly assured the remainder that there was no danger, and they retired in an orderly manner.

News and Notes.

PHOTOGRAPHIC Instruction at Chiswick.—The programme of the Acton and Chiswick Polytechnic, Bath Road, Bedford Park, W., contains the syllabus of classes in photography and photo-engraving.

MR. SIMON MOTLE, who, for many years carried on the business of a photographer at Commercial Road, Hayle, died at the residence of his son-in-law, Mr. J. Woodcock, Goonvavern, at the ripe age of 87 years.

MESSRS. SPEAIGHT are compiling for the Lady Mayoress a portrait album of her Twelfth Night guests, and children in fancy dress on their way to the studio, were one of the sights of Bond Street during the latter part of last week.

"THE BRITISH OPTICAL ALMANAC," 1905, reaches us from the offices of "The Optical Journal," Temple House, Temple Avenue, London, E.C. It contains memoranda for opticians, and addresses of members of the optical societies, and a diary for the year.

IN announcing, last week, the appointment of Mr. Bartlett as advertisement manager for Kodak Ltd., we might have added that Mr. Alfieri, who resigned the position some time ago, did so to take up the duties of illustration manager for a leading firm of newspaper publishers.

THE death of M. Paul Henry, the well-known astronomer of the Paris Observatory, took place on the 6th inst. He had been for many years associated with his brother, the late Prosper Henry, in the preparation of the French section of the International Photographic chart of the sky.

A GLASGOW branch of Messrs. Houghtons, Ltd., has been established at 74-78, York Street. Northern and Irish customers of Messrs. Houghton's should note that the Glasgow house has the telegraphic address, "Houghtons, Glasgow," and the telephone numbers 1309 National, and 4666 Corporation.

VENICE in Yarmouth.—Photographers in Yarmouth during the past few days have been taking advantage of the recent floods in Yarmouth to secure views of the town in its Venetian aspect. In some of the streets there was as much as two feet of water, and boats were rowed up and down the thoroughfares.

PORTRAITS of Royalty.—Mr. W. S. Stuart, the well-known photographer, of Richmond, attended at Claremont last week, and took portraits of H.R.H. the Duchess of Albany, H.R.H. the Duke of Saxe-Coburg, H.R.H. Princess Alexander of Teck, H.S.H. Prince Alexander of Teck.

SPEAKING at a meeting of the Classical Association last week, Professor Ernest Gardner, Yates Professor of Archaeology, University College, said that whilst some illustrated editions of the classics were poor and others useful, the lantern slide was, in his opinion, a far better instrument, and more useful alike to the pupil and teacher.

THE Secretaryship of the Royal Photographic Society has been filled by the appointment of Mr. J. McIntosh, who, until recently, has been actively connected with photographic journalism, and brings as well, to the duties which he takes from Mr. A. W. W. Bartlett, the experience gained during his successful secretarial work for the North Middlesex Photographic Society. We offer Mr. McIntosh our good wishes in his new sphere.

A SOCIETY for Cromer has been formed under the presidency of Mr. D. Dulle. Other officers are: Mr. D. Davison and Dr. Burton (vice-presidents), Mr. D. Goodyear (hon. secretary), and Messrs. C. Munday, jun., H. C. Darby, P. E. Scooter (committee, with power to add to their number). The subscription was fixed at half-a-crown. The question of rules, etc., was left to the committee to go into and report at the meeting on Thursday, January 12. The society is to be known as the "Cromer and District Photographic Society."

AMMONIA IN EMULSIONS.

To the Editors.

Gentlemen,—The letter from Mr. Henderson which appears on p. 1119 of the issue for December 30 raises the question of priority as to the suggestion for the use of ammonia in gelatine emulsion making.

Dr. Eder, in his "Handbuch der Photographie," gives credit to Johnston. "B.J. Almanac," p. 85, and Schiendl, "Geschichte der Photographie," also give credit to Johnston, but both appear to have overlooked the fact that in the BRITISH JOURNAL for December 5, 1873, p. 586, there appears a letter over the signature "W. F. T.," which distinctly suggests not only the use of ammonio-nitrate, but also of ammonio-carbonate, of silver, the actual text being as follows:

"By slightly modifying the method of making a collodion emulsion, described in your leader of September 27, 1872, a gelatine emulsion can be formed with bromide of silver in an exceedingly fine state of division.

"An emulsion prepared as follows leaves only gelatine and bromide of silver on the plate when dry. The ammonia and carbonate of ammonia evaporate with the water:

A.—Gelatine 15 grains.

Dry bromide ammonium 10 grains.

Dissolve in water ½ ounce.

B.—Nitrate of silver 18 grains.

"Convert the silver into oxide or carbonate, wash and dissolve by the addition of a few drops of liquor ammonia; make up with water to half an ounce, and then mix the two solutions A and B. After filtration through paper the emulsion is ready for use."

In the BRITISH JOURNAL for March 13, 1874, p. 122, J. W. Gough describes an experiment of precipitating the silver bromide washing and adding a few drops of ammonia, and mixing in a mortar with the gelatine.

In the BRITISH JOURNAL for September 29, 1876, J. Johnston describes the use of a new silver salt for collodion emulsion making, and says that he thinks it is ammonio-nitrate of silver. In a leaderette in the issue for November 17, 1876, it is stated that a gelatine emulsion had been prepared with the new salt (by the Editor presumably), but that it had not been tested. In the issue of November 24, 1876, p. 553, and December 1, p. 565, the results of the experiments and the method of making the emulsion are detailed.

In the BRITISH JOURNAL for 1879, p. 375, Monckhoven describes his process of preparing silver bromide by the interaction of carbonate of silver and pure hydrobromic acid, and in a later paper (p. 476) he describes the use of ammonia.

Dr. Eder in the first edition of his handbook also describes the use of ammonia and carbonate of ammonia. This appeared in the BRITISH JOURNAL for 1880.

The first communication I can find on the subject by Mr. Henderson is entitled "Cold Emulsification with Uniformity," which appears in the BRITISH JOURNAL for August 18, 1882, and which was a communication to the L. and P.

The use of alcohol in the emulsion was first suggested by a writer to the BRITISH JOURNAL in 1873 who signed himself "Ostendo non Ostendo," and who claimed for it the production of a finer grain. Mr. E. W. Foxlee, in the BRITISH JOURNAL for December 26, 1873,

states that it gives increased rapidity, and numerous writers in the succeeding years also state that the addition of alcohol gave finer grain and greater rapidity.

Mr. Henderson is quite correct in stating that his paper before the Derby Convention, 1886, was reported in the *BRITISH JOURNAL*, and it is for practically the same idea that Herr Gaedicke has been granted an English patent.

In his German patent Herr Gaedicke points out that an after ripening by the aid of ammonia is a well known fact, and says that "the ammonia which is tenaciously held by the gelatine not only alters in the course of time the sensitiveness of the plate, but by keeping the much dreaded grey margins are formed, and that by this process there is never obtained a product of determined constant sensitiveness. This is a very serious matter, for the constant character of the product is very important. As in the principal ripening process of the previous process, the gelatine is very strongly attacked, so that frequently plates are obtained to which the film floats off, and the after ripening does not attack the gelatine, it appears advantageous to prepare the emulsion unripened and to wash it, and then introduce the main ripening process, and to effect this by the mild ripening action of ammonia, and then to neutralise this. Although the opinion has been hitherto held that in the absence of excess of soluble bromide, the sensitiveness cannot be raised sufficiently, it has been proved by experiments to be erroneous. The following facts were established: (1) Even in the absence of soluble bromides the sensitiveness can be sufficiently raised. (2) A washed emulsion only requires about one-tenth the quantity of ammonia in order to obtain the same sensitiveness as an unwashed emulsion. (3) An unripened washed emulsion, made very sensitive by digestion with a little ammonia, does not lose in sensitiveness by neutralisation or saturation of the ammonia with an acid. (4) The ammonia salts formed can remain in the emulsion without doing any harm. (5) The emulsion prepared as described in (3) does not alter when kept or melted up or in coating. (6) Such emulsions give plates which keep very well, which never have grey margins, and their sensitiveness does not alter by keeping. (7) Such emulsions always give constant results by a given method of work, as the ripening process is only allowed to continue for a given time and is then stopped.

Herr Gaedicke states that he prefers to make a slow emulsion of from 1 to 5 degrees Scheiner—that is, from about 6.5 to 16 H, and D.; the emulsion is then broken up and washed in the usual way and melted at 115 deg. Fahr., and the bulk made up to twenty times the total weight of the gelatine used, and from 1 to 5 cc.m. of ammonia, triethylamine, caustic potash, etc., added, and the mixture digested from one to four hours at 104 deg. Fahr., and then an equivalent quantity of sulphuric, tartaric, citric, or oxalic acid added, and the emulsion allowed to set, and again melted and coated.

Obviously the only claim in the patent is for the neutralisation of the alkali or ripener by an acid, but we are not told how the exact quantity of acid required, say, for instance, in the case of ammonia, is arrived at, as it must be presumed that, although according to Herr Gaedicke, gelatine retains ammonia very tenaciously, it cannot prevent the escape of some during a digestion of four hours at 104 deg. Fahr.—Yours faithfully,

E. J. WALL.

Foots Cray.

THE RETORT COURTEOUS!

To the Editors.

Gentlemen,—I was told a very smart thing about the free sitting business during the past week, which I can vouch for as being true, and will no doubt interest you and your readers. A well known and very popular clergyman was down at one of the seaside resorts, preaching and lecturing. The tip-top photographer of the place wrote and

asked for a sitting. The reply was brief. "Is thy servant a hen that he should do this thing?"—Yours truly,

W. E. DIXON.

Brighthouse Photographic Company, Briggate, Brighthouse.

January 7th, 1905.

NORTHAMPTON PHOTOGRAPHIC EXHIBITION.

To the Editors.

Gentlemen,—Kindly call your readers' early attention to the alteration in dates of our exhibition (now to be February 24-March 4).

Entries will be received up to February 7, and pictures to February 17.—Yours faithfully,

E. J. H. FELCE, Hon. Sec.

The Museum, Guildhall Road, Northampton.

January 7th, 1905.

THE EMPLOYEES' UNION.

To the Editors.

Gentlemen,—I was very pleased to see the letter signed "A Ten Year Assistant" in your last issue. The well-meaning people who from time to time advocate the formation of associations for photographic assistants are doubtless actuated by the best possible motives. But these good-natured folk seem entirely to forget that photography has become a universal hobby, which makes it unlike any other business, and therefore it cannot be gauged by the usages of ordinary trade.

The idea of a trade union for photographic assistants only is absurd. Unless you can govern the wages and control the hours of labour trade unionism is out of the question, and in photography this is impossible.

Benefit societies under amateur administration are better left severely alone. If photographic assistants have any opportunity or desire to become thrifty there has existed for many years several well-established, well-organised, and reliable institutions, which will be pleased to accept their weekly or monthly subscriptions, however small, and from these old-established institutions they may be assured of receiving, in case of need, whatever benefits are arranged for.

Without in any way wishing to call in question the ability, integrity, or good intentions of the kindly people who at uncertain periods "bob up" with proposals for benefit societies, unions, and benevolent schemes for photographers, we can but remember the previous failures in this direction. Provident institutions of any kind especially require more than a sentimental or even enthusiastic few to keep them going; and if they are to succeed they must be carried out on purely business lines by experienced men, and not left to the mercy of honorary amateur organisation.—I am, gentlemen, yours truly,

DROP SHUTTER.

PULLIGNY LENSES.

To the Editors.

Gentlemen,—Where can the lenses used by Major Puyo be got? They are stated not to be expensive.—Yours truly,

Peterhead.

JAMES SHIRAS.

[We have not M. Pulligny's address, but in the "Revue de Photographie" we see an announcement from 21, Rue Tronchet, Paris, which possibly may have reference to them. Probably a letter to M. Pulligny, addressed care of Major Puyo, Photo Club de Paris, 44, Rue des Mathurins, Paris, would be forwarded.—Eds. B.J.]

A NEW HONORARY TITLE.

To the Editors.

Gentlemen,—I have just received a circular which sets forth the particulars of certain classes, in which I find an honorary title that is quite new to me. It states that The classes are to be held by a Mr. Blank ("Royal Photographic Society.") What shall we come to next?—Yours faithfully,

London, W.

F. R. P. S.

Answers to Correspondents.

- *** All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- *** Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- *** Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.
- *** For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED :—

H. Humphreys, Tring Station, Tring, Herts. Photograph of the Fleckney Family Representing Five Generations.
F. T. Taylor, Castle Square, Carnarvon. Four Photographs of Councillor D. T. Lake, Mayor of Carnarvon.

FLASHLIGHT.—I have to take a flashlight photograph of a theatre showing audience. Shall I require the lights to be lowered in the building, or will it make no difference?—S. H. S.

There is not the slightest need to turn down the ordinary lights, in fact, it is better to keep them burning, as they will not only add to the effect, but make the effect more natural.

RETOUCHING.—I shall be glad if you will kindly let me know whether there are any schools for retouchers in or about Liverpool?—ANXIOUS TO LEARN.

We know of no school in Liverpool; possibly lessons could be obtained at the Manchester Technical School, or an examination of our advertisement columns will give the addresses for postal tuition, which is quite satisfactory.

BOOKS ON STUDIO WORK.—Will you kindly favour me with titles of two or three works on general studio work, placing the one you consider best first on list? I want the book for instruction, more particularly in studio lighting and posing, etc.—C. C.

(1) "The Lighting in Photographic Studios," by P. C. Duchochois, 1s. (2) "Artistic Lighting," by Jas. Inglis, 2s. 6d. (3) "The Pose in Portraiture," No. 2 of "The Photo-Miniature" Series. You may also obtain "The Studio, and what to do in it," by H. P. Robinson, 2s. 6d.; and "The Photographic Studio," by T. Bolas, 2s.

LIST OF PHOTOGRAPHERS.—I should esteem it a favour if you could inform me if there is a list of "photographers" published, and where same may be obtained? Awaiting your reply at convenience.—P. E. MATTHEY.

Some years ago a list of photographers was published by Percy Lund and Co., but it is now out of print. Kelly's Directory of Chemists and Druggists might be useful, and still more so the Index of Standard Photographs, published by Dawbarn and Ward, 6, Farringdon Avenue, E.C., which contains a very full list of photographers.

EMULSION FORMULÆ.—1. Can you oblige me with good formulæ for slow bromide emulsion for gaslight working, and also formulæ for chloride paper (Vélox type) slow? 2. Should chloride emulsion be washed?

1. We are not aware that formulæ for "gaslight" emulsions giving black tones have been published. Our querist will understand that such formulæ are jealously guarded by the manufacturers of the papers. Chloro-bromide emulsions for warm tones are well known, and formulæ, notably that of Mr.

J. B. B. Wellington, will be found in the larger text-books. 2. Yes.

MATTY REPRODUCTION NEGATIVES.—I am a professional retoucher of six years' experience, but a brother retoucher has told me that it is important to understand the retouching of "matty reproduction negatives" to be up to date. I have never heard of them before. Are they a special kind of negative used only for reproduction work, or are they in general use? How are they retouched?—PENCIL.

We have never heard of matty reproduction negatives, though an advertisement about such things did appear in one of the daily papers. Possibly it means negatives coated on the back with varnish.

COLOURING ALBUMEN PRINTS.—I have albumenised prints to colour in water. Will you inform me if they require any preparation, or what medium I must use to make colours flow?—W. A. R.

The best thing to do is to rub the print all over with dilute solution of oxgall, made thus:—

Purified oxgall	60 grs.
Distilled water	16 ozs.
Rectified spirit	4 ozs.

Shake occasionally till dissolved. The oxgall can be obtained from any chemist. Special water-colours for tinting prints can be obtained, or, if the ordinary are used, then they should be diluted with the above mixture.

CARBON PROCESS.—Will you kindly inform me if the fumes of an oil lamp would be detrimental to carbon tissue? Gas fumes are, and I am anxious to know if I might safely use a lamp for drying purposes.—L. L. HUNT.

Whilst the fumes of an oil lamp are not so detrimental as gas, there is no doubt that they are prejudicial. There ought to be no difficulty in so arranging the drying apparatus that the heat only, and not the fumes, should have access to the tissue. An iron plate above the lamp might be arranged if a box is used, or the lamp might be placed in a chimney above the box, so as to create a current of air through the same; in this way we have perfectly dried tissue in winter in about eight hours.

INTERIORS.—I am writing to ask you which is the best way (1) to make an exposure when taking an interior of a church. Should I stop the windows from being exposed until the other exposure is made, then expose the windows? (2) And which is the best way of printing the picture? Are the windows to be blocked out until the other part is printed? (3) And is bromide paper good paper to print church interiors on? Is it better than the printing-out process? I have sent you a print. I want to make this work a speciality.—G. F. Y.

(1) Not necessary if you use a thickly-coated and backed plate. (2) It may be necessary to coat the back of the negative with yellow matt varnish, scraping this away over the windows. (3) Bromide paper is equally as good as a print-out paper, though with the latter it is often easy to dodge the negative during printing by covering portions of it.

COPYRIGHT.—Some time ago I gave a gentleman some unmounted and unregistered photographs for the purpose of making post-cards, on condition that my name was printed on them. The postcards appeared with my name in black and white, but another lot has been brought out, coloured, without my name. What I wish to know is whether, if I register (those photos which I think fit), it will stop the publication of them, and, if so, which is the best course to pursue?—F. H. C.

There is no custom of the trade as to mention of the photographer's name, so that it will be necessary for you to prove

this to have been a condition of reproduction. Assuming this to be done, you can register the photographs either at Stationers' Hall or through our publishers, and you can then take action for the stoppage of further copies without your name.

COPYRIGHT.—An artist friend has given me the rights of reproducing his paintings—for America—of sporting and cattle subjects. I am anxious to know if (1) a subject, being copyrighted here, is also copyright for or in the States and Canada. (2) Can you give the address of any good firms that would be likely to buy the sole right for reproducing them there. (3) Can you give me an idea of the value of the sole right to reproduce any or all of them? There are about two dozen or so.—CISTERCIAN.

(1) No. The United States does not subscribe to the Berne Convention. To obtain copyright in the States it would be necessary for the copy of each painting to be made in America, the photographic copyist there registering the copyright. (2) We should advise you to apply to some of the large publishing firms, such as MacLure's, Munsey, "The Ladies' Home Journal," "Collier's Weekly." (3) Impossible to say. Why not put the matter in the hands of an agent? In our advertisement pages this week you will find the announcement of at least one firm which handles such business. In regard to Canada, it was stated some time ago that British copyright did not extend to that colony, and Sir Wilfred Laurier promised that steps should be taken in the matter.

COPYRIGHT IN GROUPS.—Several groups of from eight to twelve persons each come to my studio, unasked by me, and are photographed in fancy dress costume. No order is given me by any of the individuals, nor is any agreement made to buy, but I assume if I make a satisfactory photograph I will get orders. After showing a proof the parties individually order copies from me, which I supply at a uniform price, but no one member of a group gives me an order for the other members or takes any responsibility with the order. I simply take my own chance of what orders I may get from each separate person. (1) Does the right of reproduction belong to me? (2) Am I at liberty to reproduce these photographs along with an article in a magazine without the consent of the parties photographed? (3) Can I prevent these same parties publishing the photographs in which they appear in a similar magazine? (4) Would I be at liberty to issue the same photographs as postcards?—H. B. C.

(1) It is a moot point. The Copyright Act gives the copyright to the sitter, if the photographer receives "valuable consideration" for his work. Your best plan is to get the parties in the groups to sign an assignment of the copyright to yourself. (2), (3), and (4) If you establish your proprietorship in the copyright, you can grant right of reproduction, and restrain the persons photographed from granting rights of reproduction.

STUDIO QUERIES.—1. I am erecting a studio in my garden here for professional work. It is 22 ft. by 9 ft. 8 in., height to eaves 7 ft. 5 in., height to ridge 9 ft. 9 in. I suppose this will be ample for general work? I cannot make it larger to comply with the Building Act, which ties me down to 10 ft. margin to next properties. 2. I propose using a Goerz 14 in. focus for head and shoulders. 3. Can I use comfortably a 10½ in. focus Goerz for full-length cabinets in a 22 ft. studio? If not, what focus should I get? 4. I enclose a rough plan of the ground, studio, sun-rising point, etc. Would you kindly help me as to what blinds I should use? I mean colour and material. Should there be two blinds, one holland and the other darker?—G. CLARK.

1. The studio will answer, but it would be better if it were

three or four feet longer and a foot or two wider. It would then be better adapted for taking groups. 2. This will do very well. 3. Yes, as a lens this focus will only require a distance of 15 ft. or 16 ft. between camera and sitter for a full-length cabinet portrait. 4. With this aspect of studio we should advise tolerably dark green blinds for the roof, and curtains, of "art serge," of a somewhat similar colour for the sides. We do not think a double set of blinds will be necessary if you employ one or other of the different forms of head screens now on the market.

ORTOL.—Re the article on Ortol as a good all-round developer in a recent issue of the B.J., I have tried the one recommended for bromide paper (I use Kodak plat matte), but find it acts fearfully slow, especially in comparison to metol-quinol. Even when using ortol much stronger—1 part No 1, 1 part No. 2, and 1 part water, instead of the four parts water advised—the image is an exceedingly long time in appearing. I find rodinal acts much quicker than ortol, but would very much like to know if rodinal, ortol, edinol, and adurol affect the skin like metol. The manufacturers of rodinal say "1 in 70" for bromides, but I find this no good at all—but with 1 in 20 I can get satisfactory results. Please reply to "Trooper" in your next issue, and oblige. Please say which of above-mentioned developers you consider most satisfactory and economical for general use, and oblige.

The speed of development is purely a matter of personal equation, as some like a rapid-acting developer and others a slow one. Ortol can be made to act more quickly by omitting the metabisulphite from the formula or increasing the alkali somewhat. The developers named do not, so far as we know, affect the skin, and metol only affects some people. Personally, we should always use adurol for bromide work, as we prefer the character of results obtained. As regards economy, we do not think there is ought to choose between them.

ST. MATTHEW'S Camera Club, Sheffield.—The first annual exhibition and entertainment of this club were held last week. The club was founded by the late Rev. Norman Larchin, and has produced some very creditable work. The exhibition consisted of about 200 photographic prints and enlargements, the work of members of the society. A number of enlargements were lent by Dr. Helm and other friends. Among the prints exhibited were those which gained prizes in the recent annual competition.

NOTICE.

A number of "Answers to Correspondents" are crowded out of this issue, and will appear next week.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

Formaline for Test Purposes.

The reactions of formic aldehyde with a number of organic bodies may serve as a ready means of distinguishing between substances which are occasionally employed in photography. Herr G. Glucksmann has pointed out that formalin mixed in equal parts with a solution of the substance to be identified in hydrochloric acid produces certain characteristic effects on the whole being boiled. Phenol (carbolic acid) in these circumstances gives a white precipitate; pyrogallie acid, a reddish-violet colour and precipitate; pyrocatechin, a dirty violet; and resorcin, a reddish-violet precipitate.

* * *

New Formaline Compounds. Continuing the interest of M. Lumière's recent paper on hydrosulphite as a developer, is a note in one of the French dyeing journals that these salts readily unite with formaldehyde, forming a rather complicated mixture of formaldehyde-sodium-bisulphite and formaldehyde-sodium-bihydrosulphite. The latter compound, which quite possibly may be found worth investigation as a developer, is stated to dissolve freely in water. Its other reactions show it to be a powerful reducing agent. A new antiseptic, according to a recent French patent, is prepared by heating formic aldehyde with phenol under pressure in a slightly alkaline condition. Combination takes place, and the new substance, which may prove of service in photographic mountants, does not possess the odour of phenol.

* * *

Solid Formaldehyde. The liquid state, whatever convenience it may confer upon a substance from the point of view of the actual user, has serious drawbacks to

the distribution of that substance in the trade. That formalin, the 40 per cent. solution of formaldehyde, should have secured a firm footing among photographic chemicals, despite the risks of transport and storage, is a fact which speaks for its usefulness as a hardening reagent and an antiseptic. But if the claims of a German patent are borne out in practice, it will be possible to buy it in the solid state. The method of manufacture of the suggested product is by mixing the 40 per cent. solution with dextrine to a paste over a water-bath. The operation is to be performed in vacuo, and when the pasty mass is cool, it is dried in vacuo over sulphuric acid, or other desiccating agent. The finished product is stated to be a fine soluble powder, to keep well in closed vessels and to act in solution exactly like pure formaldehyde. The marketing of formalin in the solid state would certainly win the approval of the photographic trade, and probably the presence of the diluent dextrine would not prejudice its action as a tanning agent in any way.

* * *

The Scottish Salon.

The holding of the second Scottish Salon in the Western metropolis, in succession to the two great international exhibitions managed by the Glasgow and the West of Scotland Amateur Photographic Association, and at a time when all winter festivities are in full swing, is a very bold step. There are those who consider it extremely rash. We mention this, before the extent of public and financial support is known, for the sake of discounting some remarks that will surely be made if the success should not be so great as the promoters hope. Whatever the balance-sheet may show, the principle of federation will remain unaffected. The exhibition successfully fulfils its two main aims—it brings out some good workers, hitherto unknown, and it gives to a host of Scotsmen their first opportunity of seeing the work of their neighbours and fellows. And quite apart from the Salon, the Federation gives exchange of courtesies between societies, provision of lecturers and judges, economies and advertisement for local exhibition managers, circulation of portfolio prints, and many other facilities, including a great deal of information in the annual "Blue Book," and the monthly "Secretary's Letter."

* * *

A Flourishing Institution.

The record of work submitted at the annual meeting of the Scottish Photographic Federation is one of which anybody might well be proud. The fact that this Federation has grown to thirty-four societies shows that it had a niche to fill in the world of photographic work. The government of it is distinctly popular, every society has a say in its membership, and the fact that the secretary belongs to one of the smaller

societies shows that the larger societies have no monopoly of office. The lantern-slide prize-list, too, shows that the larger societies have no monopoly of talent. The Scottish Salon is an institution that could only have been successfully organised by such a representative body, and does every credit to its promoters. It is a permanent tribute to the high quality of photographic work north of the Tweed. Such institutions as the S.P.F. can make for nothing but good, and it deserves the whole-hearted support of every photographer and every society within its sphere of influence.

* * *

Curiosity and Vanity.

Why is it that a camera is exempt from the common rule? In every other sphere of work a thing ceases to attract attention as soon as it becomes common. People no longer gaze in wonder as a bicycle passes, and they are learning to ignore the motor. But a camera!—people are as excited to-day as when the first photographer staggered under a load, and carried his tent with him. The poor man who can photograph in a public space without suffering from the posing of passers-by, is indeed fortunate. The professional suffers most acutely when baby is to be photographed. His majesty the baby must be accompanied by mother and nurse, and too often a contingent of feminine relations. It is a good rule—on paper—to exclude all, or all save one, of these retainers, making them stay in the reception-room. But what photographer can do it? By the time poor baby is posed anything may happen. If she is "good as gold" her supporters must audibly comment, or at least giggle, and the whole air is electrically charged and the tiny sitter alert to the faintest disturbance. Verily, vanity and curiosity are two of the small troubles which tend to bestow many anxious minutes on the photographer who has pride in doing good work.

* * *

Cost of Working the Daguerreotype Process.

The Daguerreotype process, which is prominent in this week's "History," was by no means a cheap one to work, more particularly in its earlier days, as the following will show. At the end of Lerebours' Treatise on Photography, 1843, is a price list of the materials required. Plates, one-tenth silver, of the quarter-size, are quoted at 3 fr. each. "Twenty-five grammes of bromine, in bottle, 4 fr. A bottle of hyposulphite of soda, containing 500 grammes, 8 fr."—roughly, 5s. 6d. per pound. Ten years later its price had become reduced to about 1s. 6d. per pound. Then, notwithstanding its high price, hypo was more lavishly used in the fixing of prints, with the view to rendering them permanent, than it is by many workers of the present day, although it is but 2d. a pound. From the above quotations it will be seen that Daguerre's process was a somewhat costly one to work. But the collodion process which superseded it was by no means a cheap one in its early days. In a price list dated 1854, three years after the publication of Archer's process, collodion is quoted at from 1s. to 1s. 6d. per ounce. Pyrogallie acid, in 60-gramme bottles, 2s. 6d., or 16s. the ounce. Absolute alcohol, 10s. the pound. The bromide of ammonium was 8s. an ounce and that of potassium 2s. 6d. an ounce. The nitrate of silver was then 5s. the ounce. Glass plates for the collodion process were—the quarter-plate size 2s. 6d. and for the half-plate 5s. a dozen. At that time patent plate glass had to be used for negatives, as the common kinds were so uneven that they could not be trusted in the printing frames. What a contrast then and now, when we purchase our plates in a sensitive condition, ready for exposure in the camera, for considerably less than half the price that the plain glass used to cost.

The Drying of Colours.

The rapidity with which a paint or ink becomes dry is intimately associated with possible progress in photographic and photo-mechanical methods. Pigment printing processes in which the pigment is applied to a film capable of selectively fixing it are among the new-comers, of which the apostles of individual control prophesy great things. A quick-drying mixture of oil and pigment is a desideratum in such processes, and of immeasurably greater importance still in tri-colour processes with half-tone blocks or collotype plates. In these connections the report of the research laboratory of the Imperial High School of Graphic Arts in Berlin may be quoted, as part of the recent work in that institution has been devoted to the drying of inks. It was found that the time required for oil inks to dry was in no way connected with the proportion of pigment which they contained, but is connected with the chemical character of the pigment. Many colours with which oil was mixed in no large proportion were found to dry extremely slowly. Among these were zinc white (with 25 per cent. of oil), cinnabar (with 20 per cent.), light ochre (with 45 per cent.), ultramarine (with 50 per cent. of poppy oil). On the other hand Prussian blue (with about 100 per cent. of oil), chrome-green (with about 100 per cent.) cobalt-blue (with 140 per cent. poppy oil), dry in one-fifth to one-tenth of the time required by the above-mentioned mixtures. A remarkable difference exists in the behaviour of chrome oxide green (anhydrous oxide of chromium), which with 30 per cent. of poppy oil does not dry quicker than the hydrated oxide green of chromium, which requires more than 100 per cent. of poppy oil. The pigments have very different effects on the drying oil, and this reaction is so great as to swamp the differences which may exist in the proportion of drying oil. The experiments suggest the advantage which can be taken of suitable combinations of pigments and oils. In other words, the pigment can be selected to play the part of a "drier," and, unlike the drier usually used, will be present in an insoluble condition, and, therefore, free from the danger of producing ill-effects if the proportion of pigment to oil becomes unduly great.

* * *

Faked Photographs as New.

"There is nothing new under the sun," but much that is old. And the old has a happy knack of reappearing long after it has been written down as defunct. The wonderful composite pictures which were the acme of photographic art forty years ago were produced just as long as the pioneer workers who perfected them held the field. New men, new methods. Photographs, printed from two or more negatives; continued to be—and are still—produced. But the light effects, the sky printings, etc., of the newer school have little which may be considered in direct descent from the old line work. Recently the old method has been revived to a commercial use, and photographs, representing "truth" rather than art, are faked from two or more negatives or prints in order that by assembling detail from several sources more realistic scenes may result. As is well known, the illustrated papers frequently give finished drawings of scenes based upon photographs, or correspondents' sketches, or "from particulars supplied by an eye witness." But photography is much used by papers, partly because photographs often give the best idea of some scene or event, and partly because in some cases photographs are cheaper than drawings. Largely to meet the many low-priced Continental illustrated papers on this matter of cost, one or two photographic agencies across the Channel are turning out very ingenious fake photographs. There are thousands of photographs in existence of scenes in Port Arthur and other places in Manchuria. But there are many pictures

of current events out there which are by no means easy to obtain. A picture of, say, a Port Arthur fort has no commercial value, but if half a dozen dead Japanese are grafted into the foreground it at once becomes gruesome and topical. If a very much alive Russian stands on the ramparts so much the better. By thus adding life and actuality to mere mundane scenes, hundreds of saleable photographs are annually produced from otherwise worthless material. Sometimes a print is made direct from two negatives, more often the additions are pasted on to the background print, the joinings retouched, and the whole rephotographed. Some of the work is very crude, and must be apparent to the editors, but by the time the blocks are made, and rapidly printed on cheap paper, there is little left to reveal any fraud. And, after all, such pictures are quite as truthful as any sketch evolved by some artist who obtains his facts and ideas from several photographs.

* * *

Death of Professor Ernst Abbe.

It is with great regret that we announce the death of Professor Ernst Abbe, which took place at Jena on Saturday last, January 14, after a long and painful illness. Professor Abbe retired little more than a year ago from the directorship of the Carl Zeiss Optical Works. His share in that institution and in the foundation of the optical glass factory of Jena will be noticed at the length which it deserves in our next issue.

WHAT IS LIFE SIZE IN PORTRAITURE?

If one looks back two or three decades we see that at that time a greater feature was made by professional portraitists of large portraits, taken direct in the camera, than is the case at the present time. At that period many of the leading opticians, both at home and abroad, made a speciality of lenses of the Petzval form for portraits up to 18 x 15 and larger, and having a diameter of 6 in. and upwards. Some (many) years ago the late Mr. Rob. Crawshaw, with the view to encouraging large portraiture, offered a series of substantial prizes for the best large portraits, both direct pictures and enlargements up to life size, and the pictures shown in competition attracted a great deal of attention in the photographic world at the time. Some severe comments, it may be mentioned, were passed on the life-size heads exhibited that were taken direct in the camera by reason of their unpleasant appearance, good photographs as they were, through the necessarily near approach of the camera to the sitter.

On the Continent now large direct portraits, but nothing approaching life size, are in much greater vogue than they are in this country, and exceedingly fine the majority of them are. It may be admitted, we think, that a large portrait taken direct, of a size, say, 16 in. or 18 in., when the camera is placed at a good distance from the sitter, as is done in Continental studios, possesses technical photographic qualities that one does not get in an enlargement from a small negative. When these large direct portraits were most in vogue in this country, wet collodion was the process employed, and, of course, the exposures were exceedingly long as compared with what would be required now with gelatine plates. However, it is not with large direct portraits that the heading of this article applies, for we imagine that few nowadays will essay taking life-size portraits direct. It is with enlargements we are dealing.

It is not many photographers who make their own

enlargements, except perhaps those of the smaller sizes, and disappointment is sometimes felt when a life-size one is received from the professional trade enlarger, and this brings us to the question—what is “life size”? The obvious and literal answer is, of course, the size of life. But does the size of life, by measurement, in a portrait always convey the idea that it is “life size”? Whether it does or not, as we shall presently explain, very much depends upon circumstances, and these circumstances are not always taken into consideration when photographers dispatch their negatives to the professional enlarger. It may be taken that the average size of male heads is about $8\frac{1}{2}$ in. from the bottom of the chin to the crown of the head—not the top of the hair—and that of women about an inch less. Now if these dimensions were strictly adhered to, in all cases the results would be unsatisfactory. Supposing, by way of example, a pair of portraits, a lady and a gentleman, were made to the above dimensions, and they happened to be the exact ones of the persons portrayed, but the gentleman possessed a rather thin face and a bald head, while the lady had a round face and a profusion of hair, dressed high on the head. Here the two pictures would look disproportionate. The gentleman's portrait would, by comparison, appear to be less than life size, while that of the lady would look larger than life size, although both portraits were, by the foot rule, the exact size of the originals.

We will here quote a case that came under our notice a little while ago. It was this. A photographer executed an order for an enlargement of a gentleman—a vignettied head and shoulders, a $5\frac{1}{2}$ in. head. The gentleman was very thin, and the portrait was taken three-quarter face and figure, and the enlargement gave every satisfaction. Another was ordered, same size, but from a different negative. In this the face and the figure were nearly full, and when this picture was sent home it was returned as being much smaller than the first one, while, as a matter of fact, by actual measurement, the head was nearly $\frac{1}{2}$ in. larger. Yet, notwithstanding this, the head in the second picture certainly looked considerably the smaller of the two.

In making enlargements attention ought to be paid as to where the pictures are to be hung. If they are to be hung high up in a lofty room the head will appear to be much smaller than it would do if hung low in a less lofty place. This is a matter that is usually taken into consideration by portrait painters, who often, when the first-named conditions prevail, paint the head an eighth or so larger than the exact size of life. Here is another example of how the apparent size of a portrait may be affected. Let us suppose that a three-quarter or half-length portrait of, say, a lady, with the hair dressed high on the head, be made the exact size, by measurement of the original, and framed with a margin. When seen at a distance, as such pictures usually are, the head will appear to be the size of life. But let the head only be cut out and framed up close, it will then, to all appearance, be much larger than life size; in fact, will be ugly in the extreme. In such a case as this, the “life-size head” should be made considerably smaller than it is by foot-rule measurement.

From what has been said it will be seen that the query as to what is life size in a portrait is not quite so easy to answer as it would at first sight appear. Our object here is to point out to those who send out their enlargements to be made the desirability of sending with the negatives specific instructions as to the dimensions they are to be made to within two definite points in the picture—say, for instance, between the top button of the coat and the top of the hair, after, of course, duly considering the frames into which they are to be put, and the conditions under which they will be hung.

IMPRESSIONS OF THE SECOND SCOTTISH SALON.

THE first impression—and it is one that grows as the show becomes more familiar—is that the principal work of art is the one which will be destroyed by its own creators shortly after the end of this month. It is the exhibition as a whole. Mr. G. D. Macdougald hit upon a truth when he humorously said at the luncheon that the Salon Committee had made the exhibition, while the contributors had only made a few pictures. A small body, with Mr. J. W. Eadie as the very strenuous acting head, has created an exhibition which has more feeling of successful design than almost any exhibition which has preceded it.

The (London) Salon, hung by Mr. Evans, is an annual triumph in this direction; but the problem set to Mr. Evans is different, and the limitations imposed upon him are different. Mr. Eadie has a much larger room, and a much larger area of pictures, so that his greater space is more crowded. He has also a few stronger high-lights than are usual at the London Salon, and a more solid mass of sombres, with little middle-tint work, and has planned each wall or panel as a vignette, with the high-lights toward the centre, and with as smooth gradation as the prints and frames will allow, to the edges. The whole arrangement is backed with a dark slate-grey canvas, and surmounted by a stencilled frieze which well supports the general effect, and that effect is restful, harmonious, distinguished. But a little gem is occasionally "skied" to make a general harmony.

It seems a pity that so much really good thoughtful work as goes to the making of such an exhibition should go unrecorded, and Mr. Eadie is wise in photographing the show as a whole, and the principal panels.

The personalities of the Scottish Salon are interesting. The Lord Provost, himself an earnest amateur, makes a perfect host, and an admirable opener of the exhibition. His speech, of simple eloquence and eloquent simplicity, was a model. Henry Coates, the president, polished, quietly enthusiastic, eminently business-like; J. W. Eadie, artistic, untiring, tending to drive others beyond their strength, but driving himself most of all; W. A. Frame, full of his secretarial work and responsibility, worried with details from every side, over-conscientious and over-anxious, but settling down to placid satisfaction as an undoubted success, was evolved out of weeks of chaos—and the Federation Secretary, the great, strenuous, straight-talking, forty-horse power force behind the whole thing, J. B. MacLachlan! Yes! they are an interesting lot of personalities.

And what is the pictorial crop? The pictures are mentioned in detail elsewhere in this issue. But here we must make a note of new men emerging. J. Craig Annan, W. Crooke, Archibald

Cochrane, and John M. Whitehead fully hold their positions; and W. A. Clark, of Birmingham (who would have suspected him of being a Scotsman?) makes a strong showing of work that is already well-known. Beyond these, however, there is much of the good and new. Charles Macdonald, with four frames, reveals a new and strong personality of the very first rank, a man who has no counterpart as to style, who comes nearest, perhaps to some of the Germans or Belgians, but who deal with much more complicated problems. His ability in decorative arrangement is quite unusual, and he places strong notes with a mastery that is his own specialty.

Another man who is good and interesting even when seen alongside one so powerful as Mr. Macdonald is Mr. G. D. Macdougald, of Dundee, one of the few "gum" workers in the show who justifies his choice of medium with every one of his works.

There is a crowd of other little-known people:—Geo. L. A. Blair, of Paisley; R. Murray, of Barrhead; D. S. Maclellan, of Blairgowrie; J. C. Robertson, of Brechin, who is both very strong and very prolific; John Hepburn, of Glasgow, who adds to his recent R.P.S. successes; A. W. Hill, of Shotts; Dr. Richmond, of Glasgow; J. B. Johnston, of Edinburgh; E. Drummond Young, of Edinburgh; Louis C. Logan, of Woking; A. W. Reid, of Greenock; J. Bruce Cameron, of Kirkintilloch; J. Peat Millar, of Beith; and Mrs. V. C. Baird, of Broughty Ferry, are all notable. And they do not by any means exhaust the noteworthy exhibitors.

The panel devoted to Alexander Keighley, as an invited exhibitor, was most worthily filled, and the work seemed very fully appreciated by many who had not previously seen it.

The other "foreign" exhibitor, Alfred Enke, of Stuttgart, was distinctly puzzling. The introduction of his pictures to British students is an act for which the Salon must be sincerely thanked, and of which its committee may well be proud. At first sight, to those who knew the work only through Mr. Enke's own fine reproductions, the originals were very disappointing, and even after repeated study some of them must be frankly admitted to be distinctly inferior to the reproductions. The original prints, in strong pure blacks and whites, lack mellowness, and emphasise strength into harshness. But for all that, they are a fine masterly exhibit. Such an example as "Devotion" (272) proves that Enke is a master of delicate silvery tone. "Born to Command" takes very high rank as a figure study of tremendous power; "Sea Surf" (253) shows that something new and good remained to be done in seascapes. And many another example is worthy of space which cannot be afforded.

THE Press Photographer.—The "Daily Mirror" in its issue of Friday last cannot contain its pride in the photographer who obtained a flashlight exposure of Mr. Chamberlain at Preston. Committees were obdurate in refusing him to make use of his "most reliable camera" (will the "Daily Mirror" tell us more about this desirable instrument?), but Mr. Chamberlain himself arrived to dispose of their objections, and offered to submit himself to the camera. He expressed the hope "that he would come out all right," but unfortunately the "Mirror" does not print his comments on the photograph as it has fared at the hands of the process-man and printer.

GLASS transparent to ultra-violet light has been recently manufactured by Messrs. Schott and Genossen, of Jena. For optical purposes it will find many uses, and radiographers in particular

expect to make use of it. Mr. J. H. Gardener, in a paper on the new glass in the current "Journal of the Röntgen Society," writes:—"It seems to me possible that the excessive opacity of the heavy ultra violet flint to X-rays may be of value. It would be interesting to try the effect of using this glass instead of the usual glass for photographic plates. It is possible that the X-rays being so completely absorbed might give rise to some effect in the glass, which would enhance that due to the X-rays themselves. The glass would also certainly be of value as a cover for barium-platino-cyanide screens, for without in any way impairing the clearness of the visible image it would form a perfect protection to the person using the screen from exposure to X-rays. There are certainly many other directions in which U V glass may be of value, and one can only hope that the demand for the material will soon enable it to be produced in quantity and at a reasonable price."

THE FOCAL PLANE SHUTTER.

I.

THE past year having witnessed a much wider adoption of the focal-plane shutter even among cameras of comparatively low price, it seems advisable to collect one or two of recently published writings on this piece of apparatus. Opinion is divided on focal-plane matters in several particulars. It is stated, for example, that the exposures made with it are always distorted—a view taken by Chapman Jones, who writes¹:—"It should never be used when a shutter at the lens is possible because it distorts the image of the moving object. If the shutter moves downwards and the man is photographed as he is running, the man's head is first photographed, then gradually his body downwards, and then his legs. But he is moving, and therefore the lower part of the image is in a more forward position on the plate than the upper. The man may be actually leaning forward and the image may show him as if he were inclining backwards. If a man in a horizontal position is falling downwards, as sometimes in diving, he will appear stouter than he really is. Other effects of exposing a plate piecemeal can easily be discovered. It must be admitted that these distortions are not often obtrusive in photographs taken with focal-plane shutters, but the effects cannot be avoided, and would be revealed by a critical examination of the picture. Therefore such shutters should never be used when it is possible to use a shutter at the lens." Quite contradictory is the experience of W. Kilbey, who pronounces strongly² for no distortion on the ground of practical work with a number of shutters.

Focal Plane versus Lens Shutters.

Then as to the efficiency of the shutter compared with others which work in or near the lens. Kilbey, again basing his statement apparently on the basis of practical work, estimates the focal-plane shutter to be twice to three times as "efficient" as one working near to the lens, "that is to say, the developable action would be as great with an exposure of 1-100th second in the former case as with 1-30 to 1-50 second in the latter."³ On the other hand, this estimate has been thought to be altogether too unfair to the lens shutters, which would have to be very bad indeed in order to have an efficiency of only 33 or 50 per cent., assuming the focal plane to pass the whole of the light to the plate which enters the camera by the lens diaphragm.

This latter point is referred to in a paper by Herr K. Martin, of Rathenow, in contrasting focal-plane and other shutters.⁴ It is pointed out that an efficiency of 50 per cent. represents a very crude type of shutter, consisting of a circular aperture covered and uncovered by the passage of a board, the square aperture in which has the same diameter as the circle across which it moves. But such an apparatus stands near the bottom of the scale of shutters, and with suitable design and mechanism shutters of efficiency up to 90 per cent. should be capable of construction, Herr Martin thinks.

Variable Focal-Plane Efficiency.

A well-made shutter of this class may thus exceed a focal-plane shutter in efficiency, for the latter may suffer in this respect if the distance between slit and sensitive plate exceeds a negligible quantity. Theoretically the moving slit should be in contact with the plate. Usually it is as near as the maker can get it. Sometimes it is removed to an extent sufficient to reduce the efficiency of the shutter. In many cameras, says

Herr Martin, the slit is 10 millimetres, often 12 to 14 millimetres, from the plate, and therefore the rays reaching the slit are spread out into a band which is broader than the slit itself. The defect from this cause becomes more marked the larger the stop of the lens, the greater the distance of the slit from the plate and the smaller the width of the slit. If, for example, the focal length of the lens is 120 mm., its aperture (F.4) 30 mm., and if the slit is 3 mm. wide and 12 mm. from the plate, the actual band on the plate will be 6 mm. in width, and the light utilised is only 50 per cent. The formula connecting the three quantities is as follows:—

Lens aperture in mm. \times distance of slit from plate in mm.

Focal length of lens in mm.

The arithmetical result of this expression is the smallest width the slit can be, if it is to employ the full aperture of the lens.

Factors in Focal-Plane Efficiency.

The relations of these factors in the efficiency of the shutter will be clearer if the simple mathematical treatment adopted by Legros⁵ be studied. In the figure, AB is the blind of the shutter, a the width of the slit, b the distance of the slit from

the plate, f the focal length of the lens, and o the diameter of the lens aperture. In this figure the action of the light takes place between F and G. But it is not constant. Between F and G the plate receives the full action of the lens. Between G and H and between E and F the action is incomplete. The effect of the light is better as the two periods G H and E F are very small in comparison to the central band E H. The "efficiency" can be regarded as represented by a fraction of which the numerator is the complete period, plus one incomplete period, and the denominator the total of the three periods. Thus in the figure—

$$\text{Efficiency} = \frac{FG + EF}{FG + EF + GH} = \frac{EG}{EH} = \frac{af}{af + oe}$$

This expression is always less than 1. To attach a practical value to it, an efficiency of $\frac{2}{3}$ means that the ideal shutter would produce the same effect with an exposure of $\frac{2}{3}$, that given by the apparatus of efficiency, $\frac{2}{3}$. The efficiency increases directly as a and f and inversely as o and e . In the construction of a shutter the distance, e , from slit to plate should be made as small as possible to obtain the best efficiency. When $e = 0$, we obtain the ideal shutter of efficiency, 1, or

⁵ Fabre's Traité Encyclopédique de Photographie, 3rd Supplement.

100 per cent., to express it in the terms which Herr Martin has chosen.

Practical Measurements of Efficiency.

The total period, E H, can be measured by arresting the slit at any point in its passage across the plate and focussing the lens on infinity. On then pointing the camera to a clear sky or some strongly illuminated surface, the width of the bright band on the ground glass can be measured. . . . By exposing, or rather under-exposing, a slow plate the limits of the bands E F and G H can sometimes be sharply discerned and the efficiency directly ascertained by measurement, using the formula already given—viz., efficiency = $\frac{EG}{EH}$.

Varying Efficiency at One Exposure.

It will at once be understood that if the course of the slit is not in strict parallelism with the surface of the plate, the efficiency of the shutter will be greater at one point than another. It may be that the want of parallelism will be sufficient to cause markings in the nature of bands running across the plate parallel with the slit. This seems to be the only explanation of faint bands of this kind complained of by a correspondent of the "Photo-Revue."⁶ The effect, as will be easily seen, is noticeable only when a narrow slit is used, as with a slit of considerable breadth is employed, the area, F G, of complete action is in greater proportion to the outer bands of incomplete action.

⁶ Nos 32 and 38, 1904.

Dark Bands in Focal-Plane Exposures.

Another defect of which this same correspondent shows one of many examples obtained by himself consists of a series of bands, irregularly alternating between light and dark, which are formed on the plate at right angles to the slit. They also occur only when a very narrow slit is used and are more liable to be formed under conditions of strong lighting. The consensus of opinion obtained from readers of the "Photo-Revue" locates the cause in the roughness or irregular surface of the opposing edges of the slit. The two edges are not perfectly smooth, and hence at some points in the slit, where two prominences face each other, the exposure is diminished and a light band is the result. In the case of a slit so narrow as, say, 4 millimetres (= 5.32 of an inch), the markings will not occur, as the light intercepted by the excrescences is then very small compared with the total amount transmitted through the slit to the plate.

The Evils of a Narrow Slit.

Both of these drawbacks need not be feared if the worker is content to avoid the use of very narrow slits. The tendency of focal-plane shutters is lately in the direction of a very narrow opening in the blind for the highest speeds. This plan possesses the advantage from the maker's point of view of permitting a slower movement of the blind. But it should not be forgotten that when a slit as narrow as 3.16 of an inch is used strictly plane and parallel surfaces become of the highest importance. On other grounds as regards the avoidance of distortion—the balance of advantage appears to lie with a broader slit moving at high speed rather than with a narrower opening passing less rapidly over the plate.

THE WEEK IN HISTORY.

The R.P.S. in Being.

TO-DAY is the fifty-second anniversary of the meeting at which the present Royal Photographic Society was founded. At four o'clock on January 20, 1853, the premises of the Society of Arts in John Street, Adelphi, housed a small company of artists, chemists, and photographers, brought together there by advertisement in the public Press. Sir Charles Eastlake, President of the Royal Academy, took the chair at this meeting, and became the first president of the society, a position which he filled until 1855. The formation of the society followed immediately on Fox Talbot's partial abandonment of his patent rights. Indeed, the exhibition of 1851 had created such interest in photography that a society would have been formed earlier but that the patents of Fox Talbot hung like the sword of Damocles over the prospects of an independent society, and threatened to be an insuperable obstacle to the progress in the art. Rules of the new society were adopted by this meeting and a date fixed for the first ordinary meeting, and Roger Fenton was appointed honorary secretary. Even this inaugural meeting appears to have wandered from business into technics, for an unknown gentleman from Scotland exhibited a series of "remarkably fine sea-views obtained upon glass," explaining that the collodion was prepared by himself and that wheat-straw entered into its composition.

January 25, 1839, was the day on which the first public exhibition of Fox Talbot's "Photogenic Drawings" took place. The date fell on a Friday, and it is usually stated that the prints were exhibited by Faraday at the usual Friday evening lecture at the Royal Institution. The Journal of the Royal Institution was not published during this period, but I am informed by the present assistant secretary that there is a note in the records

stating that Mr. Fox Talbot showed his photogenic drawings in the Upper Library of the Institution on this date, but that there is no mention of Faraday's share in the proceedings.

Vignetting in 1853.

The first vignetter of which any distinct record can be found was not the now common form employed, on the front of the printing frame, but a contrivance fixed before the camera whereby a negative in vignette was produced. In the absence of documents ante-dating the patent of John Edwin Mayall, January 25 must be the anniversary of this oft-despised effect. The word "vignette" does not occur in Mayall's description of his invention, and I am at a loss to say who introduced it into photographic parlance. Mayall, who is himself described as a "photographer," titles his patent "Improvements in the Production of Crayon Effects by the Daguerrotype and Photographic Processes," and his contrivance, which resembled a huge fire-screen, consisted of a slowly revolving disc, with a central aperture in it in the form of a large star. "The central or free open portion of this star is sufficiently large to admit the rays from that part of the object which is to be shown in strong light, or as a firm sharp image, whilst the rays from those exterior parts which are to be gradually shaded or deepened off to a dark or light background are partially intercepted by the converging points of the star. With this apparatus the intensity of the light is gradually diminished, and the pictures taken in conjunction with it possess the required softened-off crayon effect. The apparatus is applicable to every kind of camera, and by placing it at different distances from the camera different portions of the image may be softened-off. . . . It will be obvious to the practical man that the apparatus may be variously modified to produce similar results,

and especially that the pure stellar shape of aperture is not essentially necessary for the end in view, inasmuch as other shapes would answer for producing the gradation of the rays."

The Publication of the Daguerreotype Process.

"F. J. T.," whose letter appearing on another page has been handed to me, should have gone to the trouble of confirming his facts before offering them second-hand from a popular encyclopaedia. In the first place there was no meeting of the Academy of Sciences on January 17, 1839. There was a meeting on the 14th, and another on the 21st, but none between. But I can explain "F. J. T.'s" citation of the 17th. It is wrongly quoted either by him or by the "Penny Encyclopaedia" for January 7, on which day M. Arago did read a paper on Daguerre's process before the Academy of Sciences. I suppose "F. J. T." will still say, with intensified insistence, that that paper, anticipating the work of Fox Talbot, ought to have been included in "The Week in History." It ought not, as I will proceed to show, though I would much prefer that "F. J. T." should himself turn to the original paper, which appears on page 4 of Vol. I. of the "Comptes-Rendus" for 1839. If he does so, he will find that that paper is not a paper on Daguerreotype in the sense of explaining in what the process consists, but a talk about Daguerreotype, confining itself to a narration of what views Daguerre had taken, and becoming very guarded when approaching anything like a working method. In other words, Arago was telling just as little as he could about a secret process. He did say that Daguerre obtained what we now call a positive by his process, and he did say that the picture could be taken in about eight or ten minutes. And that is as much as he would disclose.

Now the point which I wish to impress on "F. J. T." is that such a paper is no publication at all. In fact, Daguerre's former partner, Niépce, did actually offer to the Royal Society in the year 1828 a paper which said just about as little as this of Arago's said about Daguerreotype. Niépce's paper was never read, and very likely Arago's never would have been if the circumstances had been different. Therefore we are justified in dismissing this note of Arago's as in the nature of the modern "preliminary paragraph," emanating from a celebrity, to whom it causes "unfeigned astonishment"—to use the stock phrase—when it gets into the papers. Perhaps I may leave "F. J. T." without a doubt if I point out that M. Arago's paper is referred to by the Paris correspondent of the "Athenæum," writing on January 16. He confesses his inability to give precise details as none have been disclosed by Daguerre or Arago on his behalf. He interviewed Daguerre, who showed him a sketch made (by the Daguerreotype process) in the pouring rain, another procured "by the moon's light," and explained that the apparatus was so little cumbersome that it was hardly noticed by the passers-by. The interviewer, with remarkable foresight, laid his finger on what is at once the glory and the evil of photography in the comment "that there is still wanting to its results something to be given by the hand and eye of the artist, and . . . the mechanical exactness of M. Daguerre's views may become monotonous." ("The Athenæum," 1839, January 26, page 69.)

THEFT by a Photographer.—Walter J. Newey, a travelling photographer, of Lord Street, Wolverhampton, was charged at the Tamworth Police-court with stealing a watch and chain, value 25s., the property of William Mobb, drayman, Kirkowen Terrace, on the 6th inst. It was alleged that the prisoner called at the house for orders and stole the watch. He was arrested the same night at the railway station by Police-sergeant Oulton. The prisoner was remanded.

Photo-Mechanical Notes.

THE SO-CALLED "HIGH LIGHT" PROCESS.

As there appear to be some interest in processes for obtaining the whites of any subject completely opaque in a cross-line screen negative, I thought it well, at the L.C.C. School of Photo-Engraving and Lithography, to get a student to make some negatives of this character by several methods with a view to determine which was the simplest way. These methods were tried, and each gave equally good results, the simplest being the exposure first with a small stop, and then for a short time with a large stop.

In the examples here shown, the subject is a pencil-drawing

Fig. 1.

copied to same size. The cross-line screen used is of 133 lines to the inch ruling, and its distance from the plane of the plate five millimetres. Both had an exposure with F. 64 (i.e., 1-128th of camera extension) of $2\frac{1}{2}$ minutes, and a supplementary exposure in the case of the ordinary half-tone of 20 seconds with F. 22 round stop (i.e., 1-44th of camera extension, Fig. 1). In the case of the high-light result, the supplementary exposure was made with a square stop, the side of which was equal to the diameter of F. 16 (i.e., 1-32nd of camera extension), and the time given was 12 seconds. This negative was slightly reduced, then intensified with lead, with the result that the high-light or ground of the picture was rendered completely opaque without affecting the lines at all (Fig. 2). While such negatives are

and snap off. The writer having experienced these difficulties devised a simple appliance (that can be made by any practical man) to obviate these troubles.

Procure a piece of sheet lead about 3-32nds of an inch in thickness, and cut some strips 4 in. by 2 in. or larger, according to the size of

A. Copper plate. B. Tab for lifting. C. Plate grip, which can be tightened by squeezing between thumb and finger. D. Foot to prevent plates touching bottom of etching dish.

plate to be etched. Fold a $\frac{1}{4}$ of an inch from the end over two or three times, see fig. 1. Then bend up as in fig. 2. Now take a piece of waste copper and bend the lead over, see fig. 3. And finally as in fig. 4. Fig. 5 will explain matters more fully. You will now have a useful appliance to add to your etching bench. W. J. SMITH.

A Line Etching Difficulty.

In the corner of Messrs. Penrose's "Process Work," wherein readers compare notes and help each other out of difficulties, is the reply of Ernest S. Foden to a reader, who writes:—I occasionally find that after the first bath, as soon as the plate is touched with the roller the work picks off, especially in the large spaces of solid and becomes quite porous. Why is this, and how can it be avoided to save waste of time and metal? Let me say at once the printer is to blame for line-etcher's difficulty. There are several reasons for the work picking off as described. The most important is the using of ammonia a little too strong in the developing to clean and thin down an over-developed plate. This takes the nature out of the slight coating of ink and turpentine used previous to developing, and although the printer has no difficulty in being successful with his final roll up, or powdering in with bitumen, yet it is obvious that where the ammonia has robbed the development coating of its grease, water will be underneath, or intermixed, and the etcher's first bath will assuredly find the weak spots, and etch through and under, taking all support away and causing these weak portions to stick to the roller as soon as it passed over them. Another reason is the using of a very stale nitric-acid-alum bath previous to coating the plate with albumen. This causes a very dirty and dark oxide to form on the plate, and if not sponged vigorously before sensitising leaves portions of the oxide on, making a false surface which the nitric acid soon gets under, causing the picks off. Another reason—and this only applies to bitumen resist, is burning the plates in inefficiently or excessively. If the former, the appearance of the image will be a dead brown, and parts will rub off with the pressure of the finger. This explains itself why it should be porous, etc. If the latter, the nature will be taken out of the ink and the bitumen, giving the bitumen no grip on the zinc and making it too brittle. The surface will be rough and the colour varying from dark brown to a brown black. The acid very easily etches through this resist, and the roller soon cracks the brittle surface, fetching pieces off. A plate properly burnt in should have a smooth and glossy image of a rich chocolate colour. The only method that I know of in dealing with such cases as mentioned is to make the first bath short and sharp, to wash off the gum immediately it is put on, to get just sufficient ink on the roller to cover the plate in the first three or four rolls of the roller. The less rocking, sponging, and gumming that can be given the better, it will prevent further moisture from getting under, and together with less rubbing and

rolling will tend to give the plate the benefit of doubt. A far better and wiser plan for avoiding the waste metal box is to get the printer to pay a little more attention to his work."

A Recipe for a Stop-out.

Replying in "Process Work" to the request of a correspondent for a stopping-out solution for acid resist, adapted to zinc or copper, Herman J. Schmidt advises shellac: "Its acid-resisting quality is perfect and, above all, it is cheap. Take some brown shellac, say 1 lb., and put this into a tin; now get some wood alcohol and pour it on the shellac so that it is all covered up in the liquid. This will dissolve in a few hours, after which you put in a little methyl violet, say about two drachms, to colour the shellac resist, so that you can see where you are stopping out. This dries almost spontaneously, when putting on. When you wish to remove it, heat your plate well and pour wood alcohol over it, rubbing well with a good stiff brush and your resist will come away. I am sure that you will find this the very best stopping-out varnish of any that may be recommended to you; use this by all means. I think that for cheapness this cannot be beaten, and it will please you very much. You see, wood alcohol is not more than three or four shillings a gallon, shellac about two shillings a pound, and the methyl violet about 10d. an ounce. Of course, as you use a great amount you can make this cheaper still by buying barrel lots, which comes 40 per cent. cheaper."

PHOTO-MECHANICAL PROCESS PATENTS.

NON-INFLAMMABLE CELLULOID.—No. 9,277, 1904 (George E. Woodward, 94, Shaftesbury Avenue, London, W.).—The process consists in mixing the celluloid with liquefied fish glue, with an addition of gum arabic, gelatine, and rape oil. To one kilogramme of celluloid are added one and a half litres of liquid fish glue, 400 grammes of white gum-arabic, 100 grammes of white gelatine, and 40 grammes of rape oil. The substance to be added to the celluloid must be of a liquid syrupy consistency. The process is carried out in the following manner: The liquid fish glue with the gum-arabic is put into a receptacle of glass, china, or the like, and left to soak for twenty-four hours in a very dry place open to the air, therefore uncovered. Then the receptacle with its contents is placed on a water bath and stirred, for instance, with a stirrer of china or the like, until the gum has become perfectly liquid. The temperature of the mixture must not exceed 25 deg. C. Then the gelatine is added and stirred until it is quite dissolved, so that there is no more solid residue. The mixture is then lifted off the water bath and rape oil is added to it while stirring continuously, when, after being thoroughly mixed, it is left standing about 24 hours to cool. Before it is quite cold it is put through a sieve, in order to remove any solid pieces. After the soaking, dissolving, and cleansing by means of the sieve, it is left standing in the same place open to the air. Any scum formed during the cooling is always removed. For the treatment of the celluloid a perfectly clear colourless syrup should be used. The celluloid to be treated must be in a glass or china receptacle or the like, in a syrupy state. The mass containing fish glue is poured in by drops while carefully stirring, preferably in the middle of the celluloid, and gradually increasing the stirring surface. After a thorough mixing the celluloid is ready for use, and on coming into contact with flame does not ignite. The solution of fish glue used during the process can be obtained by letting 200 grammes of fish glue soak in a litre of cold distilled water. It is then passed through a sieve, and any parts kept back are crushed, so that they are completely mixed with the water; 10 grammes of kitchen salt are added to clear the mixture, and then it is again filtered.

PRINTING APPARATUS.—No. 4,171, 1904 (E. Luboshey, 11, Cromwell Street, Glasgow).—The printer is a box in which is a lamp and an arrangement whereby a roll of sensitive paper can be drawn off one roller, taken over the negative, and wound on to a second roller. The back of the paper is protected from light by a wrapping of non-actinic fabric or paper. The first of these claims is for "A photographic apparatus for printing and like purposes, characterised by a box or chamber, which is provided with means for giving artificial light, means for giving a non-actinic light, means for moving the sensitised material, and means for shutting off the actinic light from the sensitised material at such times as the material is being removed, substantially as described."

RELIEF PHOTOGRAPHS (Friedrich Gärtner, 43, Tanus Strasse, Wiesbaden, Germany).—(1) The improved process of making relief portraits, consisting in printing an impression from a photographic negative or the like on a sheet of sensitised porous unsized paper, stretching said impressed sheet in a frame, coating the back of the sheet with glue, applying over the glue a thin layer of plastic compound capable of becoming subsequently hard, and modelling the picture from the front against a board by means of modelling sticks. (2) The improved process of production of relief photographs or the like, consisting in printing an impression from a photographic negative or the like on a sheet of porous unsized paper, sensitised with potassium bichromate and nitrate of silver, toning, fixing, and drying the impressed sheet, stretching the sheet on a skeleton frame, moistening the impressed side, coating the back of the sheet with glue, applying over the glue a thin layer of glaziers' putty, covering the surface of the putty with powder, such as French chalk, and modelling the picture from the front by means of a board and modelling sticks, and allowing the backing to harden. (3) A modification of the process set forth in claim 2, wherein instead of putty a backing of wax is employed, which wax is removed when the modelling is completed, and the depressions on the back of the picture filled in with suitable hardening compound. (4) The improved process of and means for the production of relief photographs or the like, substantially as described.

Exhibitions.

EVESHAM CAMERA CLUB.

LAST week an exhibition of photographs was held in the Council Chamber at the Town Hall. An excellent collection of prints was shown by members, including contributions from Messrs. O. G. Knapp, W. Cox, Buckley Bent, A. W. Ward, R. C. Mawson, C. C. Moberley, E. H. New, W. Lean, and others, but the organisers felt that members might have supported the venture in this way to a greater extent than they did. The prints exhibited showed that the club, though only recently established, has already attained a high standard, and the prints in landscape and architecture were of excellent quality, but, with about two exceptions, portraits and figure studies were absent. An interesting feature of the exhibition was the collection of record and survey prints, about fifty in number. These included photographs of churches, old houses, and so on in the town and neighbourhood (some of which have been recently demolished) the borough maces and loving cup, and other objects of a like nature; these photographs are printed in a permanent process, and will now be presented to the Public Library for safe keeping for the future. Most of the record and survey photographs of view on Wednesday were taken by Mr. O. G. Knapp and Mr. A. W. Ward. The Camera Club hope in time to furnish the Public Library with a collection of

photographs which will be not only interesting, but in many ways valuable. Another prominent feature of the exhibition was the collection of old local prints, etc., by Mr. O. G. Knapp. Lantern slides by Messrs. W. Cox, R. C. Mawson, and W. R. Coulter were shown on the screen during the evening.

ALDERSHOT CAMERA CLUB.

THE following were the awards made at this exhibition, which was held last week, by Mr. W. D. Welford. Class A.—Open to members of affiliated societies. Gold medal withheld; silver medal, Mr. F. Judge, Hastings; bronze medals, Messrs. Kimber and Kay, Southampton. Class B.—Affiliated clubs collective exhibit of four pictures. Prize two guineas, Southampton Camera Club. Open-class postcards, silver medal, Mr. F. Judge, Hastings. Landscape, members, gold medal, T. Stratton. Portraiture and animal studies, photo outfit, Mr. T. Stratton. Architecture, silver medal, Mr. E. H. Orange. Hon. mention, Mr. J. T. Belton. Members' lantern slide, Mr. J. Russell. Good loan collections were exhibited by Kodak, Limited, the Royal Photographic Society, and the Ozotype Company.

HASTINGS AND ST. LEONARD'S PHOTOGRAPHIC SOCIETY.

THE exhibition was held in the Public Hall, Hastings, from January 11 to 13. The opening ceremony was performed by Major Freeman Thomas, M.P. In addition to the prints arranged in the various classes, there was an exhibit of more than ordinary interest in the shape of a number of photographs taken with Kodaks by her Majesty the Queen, H.R.H. the Princess of Wales, H.R.H. Princess Henry of Battenburg, H.R.H. Princess Charles of Denmark, Princess Victoria, and H.R.H. the Duchess of Fife.

The following is a list of the awards:—Gold medal and the best picture in the exhibition: A. E. Coleman.

OPEN.

Champion Class: Silver medal, A. E. Coleman; bronze medal, B. C. Wickison.

Landscape, Seascape, and River Scenery: Silver medal, C. D. Kay; bronze medal, C. E. Walmsley.

Portraiture and Figure Study: Silver medal, H. Cross; bronze medal, John Smith.

Architecture: Silver medal, A. E. Henley; bronze medal, Louis J. Steele.

Flowers and Still Life: Silver medal, A. E. Henley; bronze medal, E. Seymour.

Lantern Slides: Silver medal, E. Seymour; bronze medal, H. S. Warschawski.

For pictures rejected at the Photographic Salon and the Royal Photographic Society's Exhibition of 1904: Silver plaque, S. G. Kimber; silver medal, J. C. Warburg; bronze medal, John Smith.

MEMBERS.

Silver medal, H. Cross; bronze medal, John Smith.

Silver medal, A. M. Apel; bronze medal, J. H. Spree.

Awards: Fred. Judge, A. M. Apel, and J. H. Spree.

Bronze plaque, H. O. Bannister.

THE SCOTTISH NATIONAL SALON.

Specialty Reported.

THE Scottish National Salon is undoubtedly the Scottish exhibition, and a place on its walls has already become the hall mark of quality, and rightly so, when one considers that the selection of the pictures is entrusted to Scotsmen of the world-wide reputation of Messrs. J. Craig-Annan, Archibald Cochrane, and Wm. Crooke, men of widely dissimilar modes of expression, each a master in his own sphere, and each recognised as an authority in the art he adorns—a more com-

plete trio it would be difficult to find. The Salon since its inception last year has had the support of the leading men in Scottish photography, and it is confined to Scots at home and abroad, it is evident that a good estimate can be formed of the position of photographic art in Scotland. The entries sent in totalled nearly 700, and of these 325 were hung, exclusive of the invitation sections and the contributions of the Selection Committee. The decoration was undertaken by Mr. J. W. Eadie, convener of the Salon Committee; the walls were draped with green surmounted by a frieze of Scotch thistle in a decorative design, the walls being panelled by a green stained strip of wood, the whole forming an admirable background for the display of the photographs. A walk round the rooms clearly indicates that the exhibition is not "local," but a national demonstration of the photographic art of the country. An impartial critic must admit that, while there is a weakness here and there, the general trend of the work reflects honour on the country of its origin. Time was when Scotland was an unconsidered factor in the world of photographic art, though those who relegated it to that position must have overlooked the notable work of D. O. Hill; nowadays, with such men as Craig-Annan, Cochrane, Crooke, Whitehead, Moffat, Patrick, and many others of more recent "arrival" (you can see their work at the Scottish Salon) Scotland can proudly hold up her head alongside the other countries of the world, and to judge by a speech made at the official lunch after the opening of the Salon, means to do so.

The Scot while clannish, is not self-contained, and by inviting two "foreigners" to exhibit at the Salon a valuable opportunity is afforded the stay-at-homes of comparing their own work with that of workers beyond the borders.

Enke's work, a notable exhibit, is mentioned elsewhere in this issue, and Keighley's is so well known to our readers, by reputation at least, that further comment on it is useless.

J. Craig-Annan sends five prints, including his famous "Harrington Mann, Esq., and Children," although many preferred his ever-charming "Ladies of Verona."

Archibald Cochrane only shows two prints—his much-discussed "Labour" and a beautiful panel picture of cattle and trees, "Summer Pastoral."

William Crooke sends four specimens of his work; these may be taken as representing the high-water mark of professional photography. "Miss Kate Douglas Wiggin" is reproduced in the catalogue, although his strong, simple portrait of "Henry Irving" is, perhaps, a more popular exhibit.

Dan Dunlop, one of Scotland's younger professionals, has had no less than fourteen works accepted. His exhibits show a wonderful range of subject, with merit of execution in all, and the fact that he has been able to secure recognition from the Selection Committee in so many branches of photography stamps him as a man of great versatility.

J. W. Eadie has several strong exhibits, his portrait of himself being an admirably executed piece of work; perfect in balance and unstudied in pose, it will rank as one of the best things that Mr. Eadie has done.

Arthur Hawes has a large exhibit; in landscape his "A Snow-capped Town," an effective snow picture, and "A Frosty Morning—Ayr Harbour," are noteworthy, while he has a beautiful example of portraiture in "A Lady M.A."

John Hepburn maintains his place as a delineator of Scottish home life, his "Grannie's Tired Bairn," "The Village Doctor," and "When Once Life's Day Draws Near the Gloaming," being delightful transcripts of the home life of the people—the story is simply, truthfully, and effectively told; particularly telling is the calm, resigned, and yet wistful expression of the old dame in the last-named picture.

A. W. Hill, one of the new men who made his debut at last Salon,

is gaining confidence and improving decidedly in his gum prints. Mr. Hill is a gum enthusiast, and has really obtained the mastery of his process, and it serves his will instead of the opposite, as is too often the case. His figure studies are delicate and free from that clogging up in the shadows, so often seen, and his landscapes and harbour scenes are strong and decided in their treatment. In a very short time he has taken front rank amongst Scottish workers. If we were to specially instance any of his exhibits it would be "Beauty's Dawn" and "Study of a Head" (16), delightful examples of gum work.

G. D. Macdougald, the new President, is another gum enthusiast, free from the out-of-focus habit so much affected in this work. His exhibits on the present occasion are dainty little pictures—perhaps just too small for effective treatment by this process—with a luminosity in the shadows that is noteworthy.

Charles Kirk has some telling natural history studies.

J. Peat Miller has two examples hung, one a pretty picture of a chubby bairn.

A. C. Milne has a convincing harvest scene, "The Crofter's Hairst."

John Moffat, with "Principal Rainy, D.D.," and other two exhibits, represents, as he has for long so ably done, admirable technique wedded to artistic conception; he is a striking example of thoroughly good, honest work.

James Patrick has not such an outstanding exhibit as we expect from him, though his "At the Cottage Door" is an echo of former memories; his "When Day Expiring in the West" is one of his admirable farm-life pictures—quiet and restful.

Dr. Richmond has two strong figure studies in "A Foster Mother" and "A Clay Modeller," while a strong, perhaps rather heavy, seascape illustrates the title—"How calm, how beautiful comes on The stilly hour when storms have gone."

J. C. Robertson has a large exhibit, his "A Picture Book" being reproduced in the catalogue.

P. G. Terras shows a pretty picture of "A Spanish Maid."

C. M. Wane returns as an exhibitor with a number of pictures showing good technique and absence of conflicting tones.

John M. Whitehead has a notable exhibit. All his work exhibits a delicacy of execution that is refreshing in these days of broad effects and disregard of detail. "La Tulipe" is as charming as ever, but "Briar Roses" appears more delicate; the fragility of these blooms is admirably rendered. In his landscapes, "Desolation," "November Night, 1903," and others, compete for recognition, and the spectator is apt to halt between two opinions—all are good, and it is somewhat difficult to differentiate.

E. Drummond Young has good examples of portraiture. John Spark has also a good print, although nothing approaching his famous "In Pensive Mood" of last Salon.

We have only touched the fringe of exhibits; a detailed criticism is beyond the possibilities of our space.

FORTHCOMING EXHIBITIONS.

January 14-23.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

January 20-21.—South Essex Camera Club. Hon. Secretary, T. Mitchell, 180, Browning Road, Manor Road, E.

January 23-28.—Lancaster Photographic Society. Hon. Secretary, R. T. Simpson, 21, Cheapside, Lancaster.

January 28-February 12.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grand-Armée, à Marseille.

January 31-February 4.—Cardiff Windsor Amateur Photographic Society. Hon. Secretary, Mr. G. Gallon, 37, Hamilton Street, Cardiff.

February 6-11.—Blairgowrie and District Photographic Association. Hon. Secretary, Wm. D. M. Falconer, James Street Cottage, Blairgowrie.

February 15-March 15.—International Exhibition Artistic Photographs, Vienna. Hon. Secretary, Dr. Reiniger, Camera Club. Largerplatz No. 3, Vienna III., 5.

February 16-18.—Norwich and District Photographic Society. Hon. Secretary, E. Peake, Rydal House, Earham Road, Norwich.

February 21-March 7.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

February 24-March 4.—Northampton Photographic Society. Entries close February 7; for pictures, February 17. Hon. Secretary, E. J. Felce, 83, Adam's Avenue, Northampton.

February 25-March 4.—Birmingham Photographic Society. Hon. Secretary, Lewis Lloyd, Norwich Union Chambers, Congress Street, Birmingham.

March 4-11.—South London Photographic Society. Hon. Secretary, H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 7-14.—Brentford Photographic Society. Hon. Secretary, F. H. Read, Ferndale, Clifden Road, Brentford.

March 20-25.—The Cripplegate Photographic Society. Hon. Secretary, John B. Parnham.

March 27-April 1.—Leicester and Leicestershire Photographic Society. Entries close on March 20, 1905. Secretary, R. Warden Harvey, Oriental Cafe, Market Place, Leicester.

April.—International Exhibition, Genoa. Sec. Gen., Piazza Fontane Marose 18, Genoa.

April 3-15.—Photographic Society of Ireland. Hon. Secretary, R. Benson, 35, Molesworth Street, Dublin.

April 7-May 8.—International Artistic Exhibition, Berlin. Director, Herr Franz Goerke, Maassenstrasse 32, Berlin, W.

May 1-31.—International Exhibition of Photographic Picture Postcards, concurrently with the 10th Salon. M. le Secrétaire Général du Photo Club de Paris, 44, Rue des Mathurins, Paris.

June.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITION.

March 31.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Limited, Ilford, E.

THE monthly prize in the Austin-Edwards Film Negative Competition has been awarded to the Rev. W. C. Hoke, St. Columb, Cornwall, for his negative "Study of a Child."

THE "Graphic" Photographic Competition.—The first of three art supplements appears in the current issue of the "Graphic," containing reproductions of selected photographs in the recent competition. The place of honour is occupied by M. Pierre Dubrenil and among the other photographs reproduced we note the work of J. Cruwys Richards, Birmingham, and Clive Holland, Bournemouth. Our contemporary comments on the large proportion of work submitted which bore evidence of care and judgment on the part of the photographer. One lesson of the competitions seems clear—that the amateur is no longer content with merely touching the button and snap-shotting under almost impossible conditions.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents were made between January 2-7, 1905:—

TRIPODS.—No. 23. "Improvements in or connected with tripod stands." J. Ashford, Prudential Buildings, Corporation Street, Birmingham.

PRINTING FRAMES. No. 27. "Improvements in picture and photo-printing frames." Wm. Herbert Milnes, Birkbeck Bank Chambers, High Holborn, London.

DARK SLIDES.—No. 118. "Improvements in photographic dark slides or plate holders." Arthur Lewis Adams, 26, Charing Cross Road.

VIEW FINDERS.—No. 119. "Improvements in view finders." A. L. Adams, 26, Charing Cross Road, London.

LENS MOUNTS.—No. 119. "Improvements in photographic lens mounts." A. L. Adams, 26, Charing Cross Road, London.

CAMERAS.—No. 120. "Improvements in photographic cameras." A. L. Adams, 26, Charing Cross Road, London.

ROLL-HOLDER.—No. 190. "An improved roll-holder or film package, and adapted for use in connection with photographic cameras." Wm. Albert Edwards, 51, Vant Road, Tooting, London.

OPTICAL COMBINATION.—No. 322. "To take several photographic records in one operation and with one lens, the recorded images being in one plane." Otto Pfenniger, 105, Hythe Road, Brighton.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

BOXES FOR NEGATIVES.—No. 3,773, 1904. (Joseph Hart Balfour, Walnut Tree Villa, Yiewsley.) The box consists of a body, in the bottom of which one or more yielding pads are fixed, a lid having one or more yielding pads fixed thereto in corresponding positions, between which two sets of pads the negative or other

like article is placed, and means for fastening the lid to the body of the box so as to cause the negative or other article to be securely held between the two pads.

MESSRS. LONGMANS AND Co. have in the press a translation by Mr. J. Garcin of Blondlot's papers on N-rays, which he communicated to the Academy of Sciences, Paris. The volume will contain additional notes and instructions for making phosphorescent screens for observing the rays.

A NEW industrial apparatus for generating oxygen and hydrogen gas in commercial quantities by decomposing water with the electrical current has been brought out by the Maschinenfabrik Oerlikon, near Zurich. A cubic metre of oxygen and two cubic metres of hydrogen are produced by an electrical power of about 12 kilowatt hours.

New Books.

"Annuaire Général et International de la Photographie, 1904." Edited by Roger Aubry. Published by Plon-Nourrit and Co., 8, Rue Garancière, Paris. Price 5 francs.

This excellent annual contains a very copious summary of the advances made in the various branches of photography, such as optics and photo-chemistry, astronomy, photomicrography, radiography, stereoscopy, colour photography, and photographic materials and apparatus. A useful section is that devoted to a summary of all the legal cases in connection with photography that have arisen in the year, and the meetings of the leading societies and exhibitions. A list of patents, chemicals, societies, both English, French, and German, dark rooms, and dealers, with some original articles by the leading French writers, completes a useful volume, which is well illustrated by textual and full page illustrations.

"Photographischer Almanach, 1905." Edited by Hans Spörl. Published by Ed. Liesegang. Price 1s.

For the twenty-fifth year this little volume makes its appearance, and contains a series of original articles by various well known writers, a brief summary of the more important advances in technical work, and a review of the latest introductions in apparatus and materials. The book is also well illustrated.

"Die Photographische Kunst im Jahre. 1904." Published by W. Knapp, Halle, Germany. Price 8 Marks.

The third yearly issue of this German annual appears as hitherto, under the editorship of F. Matthies Masuren. It reproduces and criticises chiefly German and Austrian work, though apparently the aim of the editor is to make his pages international. If that be so he grants a disproportionate share in the space to the American Secessionists, to the neglect of French and English work. We could have spared a few pages of Secession for some of the work of, say, Demachy or Puyo. Many of the German photographs are mediocre, but a few are the very best in the volume. If only that it reproduces the works of M. Spitzer, Heinrich Kühn, R. Duhrkoop, and W. Weimer, the book is worth possessing. The production is excellent. It is faultlessly printed on a tinted paper, and contains a number of supplemental plates, among which is a charming piece of three-colour, by M. Miethe.

"Die Bildmässige Photographie." Part I. (Landscape), 1904. Published by W. Knapp, Halle, Germany. 5 Marks 50.

In these handsome quarterly issues the publishers bring together photographs by workers of very widely separated characters, though all would be classed as advanced "pictorial photographers." The first is devoted to landscape, and includes some thirty to forty reproductions of work which has appeared within the last few years. A succeeding issue is to deal with portraiture.

"Wellcome's Photographic Exposure Record and Diary, 1905." Published by Burroughs, Wellcome, and Co., Snow Hill Buildings, London, E.C. 1s.

A guide to exposure in negative making and printing—that is the chief function of the now familiar light-green volume which makes its yearly appearance from the gloomy precincts of Snow Hill Buildings. The service which it renders in this direction is not emphasised in the title as it might be, so that we may be forgiven if we explain to those who know it not that a calculator and tables provide for the determination of exposure under extremely varied conditions. In this edition of the "Record" the light tables have

been brought opposite the calculator, and each month's table being torn out, the next is exposed to view. Hence the labour of setting the calculator is reduced to a vanishing quantity. In the body of the pocket-book a new feature is the provision of pages for a record of exposures given when making prints or lantern slides from certain negatives. But the convenience of the book as a diary and record will possibly appeal less to the amateur worker than the notes on the factors which enter into exposure and on nearly every operation concerned in the making of a photograph. These are given as concise memoranda, and are carefully indexed. Altogether the "Diary" appeals to a very wide circle, and there is no photographer, if our own experience is any criterion, but will find constant occasion to make use of it. As usual, there are two editions, one for the Northern and one for the Southern Hemisphere, each also in a cover of red buffing grain, at 1s. 6d., in addition to the 1s. canvas edition.

New Materials.

RECEIVED.—"Wellington" Plates (Wellington and Ward, Elstree, Herts). The following brands of newly-issued plates will be reviewed in due course:—"Landscape" (100 H and D), "Speedy, Special Rapid" (250 H and D), "Iso Speedy" (H and D 250), "Lantern" (H and D, 5), and "Photo-Mechanical."

"The Kodak Rapid Printer." Sold by Kodak, Limited, 57-61, Clerkenwell Road, London, E.C.

The convenience of exposing bromide prints in the dark room without disturbing the conditions of illumination is one which makes for comfort as well as for rapidity. Eye-strain, it has been found, is caused by constant change from the yellow or red lamp into a brighter and white light more than by prolonged work in a non-actinic illuminant. There is thus a double reason for adopting the system of exposing bromide paper, for which the apparatus of Messrs. Kodak, Limited, provides. The "Printer" consists of a chamber, ruby-windowed, containing an incandescent gas burner, the light of which is scattered by reflection from a surface of white enamel paint, and reaches the negative through ground glass. The result is an equal distribution of the light, which, except through the red or yellow filter, never escapes into the dark room. The printer is made in two sizes—for whole plate (price £1 17s. 6d.) and for 12 x 10 (price £2 7s. 6d.) In each case smaller negatives can be printed just as conveniently as those of the full size for which the apparatus is made, and the sensitive paper is adjusted in place on the negative by yellow light.

TEN thousand photographs of natural history subjects is the total which Mr. Kearton named, at a recent lecture, as the result of the labours of his brother and himself. To obtain them they had travelled nearly 20,000 miles, from Shetland in the North to Sussex in the South, from Essex on one side to the West of Ireland on the other.

PHOTOGRAPHING Army Horses.—The Army Council has approved of photographs being taken of the different kinds of horses used in the Army, for record purposes in the office of the Director of Transport and Remounts. The horses selected are to be of the best type, and are to be photographed in "watering" and in "marching" order, and the photograph of each animal is to be accompanied by a full description, giving its Army number, height, age, nationality, etc. The photographing will be carried out by the School of Military Engineering.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Jan.	Name of Society.	Subject.
23.....	Camera Club	<i>A Landscape Painter in Japan.</i> Mr. Alfred East, A.R.A.
23.....	South London Photo. Society....	<i>The Carbon Process.</i> Mr. W. F. Slater.
23.....	Southampton Camera Club	<i>Photographic News Prize Slides.</i>
23.....	Luton Camera Club	<i>Conduct Chloride Papers and Toning.</i> Demonstrated. Mr. W. H. Cox.
24.....	Royal Photographic Society	<i>Some Problems in Shutter Design.</i> Mr. William Taylor.
24.....	Sheffield Photo. Society.....	<i>Bromide Enlarging.</i> Demonstrated. Mr. George Tomlinson.
24.....	Brentford Photo. Society	<i>Various Tones on Paper by Development.</i> Mr. E. J. Smith.
24.....	Birmingham Photo. Society.....	<i>Exhibition of Prints and Lantern Slides.</i>
24.....	Nelson Photographic Society	<i>Bourneville: The City of Pines.</i> Mr. Imman Whittaker.
25.....	Everton Camera Club	<i>Cameras and Pictures.</i> Demonstrated. Mr. Hesketh of the Thornton-Pickard Company.
25.....	North Middlesex Photo. Soc.	<i>The Trend of Photography.</i> Mr. S. H. Fry.
25.....	Boro' Poly. Photo. Society	<i>Points in Pictorial Photography.</i> Mr. A. Horsley Hinton.
25.....	G.E.R. Mechanics' Institution	<i>Platinum Printing.</i>
25.....	Photographic Club.....	<i>Various Tones on Papers by Development.</i> Mr. E. J. Smith.
25.....	Rugby Photographic Society	<i>Photography of Still Life.</i> Mr. L. Cumming, M.A.
26.....	Leigh Photographic Society	<i>Carbon Printing.</i> North Wales. Mr. H. W. Coupe.
26.....	Southport Scientific Societies	<i>A Life's Tour in Ire'and.</i> Mr. Fred. Clibborn.
26.....	Hull Photographic Society	<i>Natural History Photography.</i> Mr. Riley Fortune, F.Z.S.
26.....	Birmingham Photo. Society	<i>Annual Dance.</i>
26.....	Watford Camera Club.....	<i>The Toning of Bromide Prints, and Intensification and Reduction of Negatives by Tabloids.</i> Demonstrated. Burroughs, Wellcome & Co.
26.....	London and Prov. Photo. Assn.	<i>Microscopic Projection.</i> Mr. Freshwater.
26.....	Liverpool Amateur Ph. Soc.	<i>Competition Pictures on View.</i>
26.....	Richmond Camera Club.....	<i>India and Ceylon.</i> Mr. J. D. Gibson.
26.....	Camera Club.....	<i>Wave Phenomena.</i> Mr. Vaughan Cornish, D.Sc.
27.....	Boro' Poly. Photo. Society	<i>Matt P.O.P. and Platinum Toning.</i> Mr. G. W. Francis.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEMBERS' meeting was held at the Royal Photographic Society, 66, Russell Square, on Friday, the 13th inst., Mr. Alfred Ellis, Past President, in the chair.

The Chairman said he was sorry to notify that their President was, in consequence of a bad attack of influenza, unable to be present that evening. He proposed with their concurrence to convey to Mr. Turner their sympathy and best wishes for his speedy recovery.

The Assistant Secretary drew the attention of the members to certain additional paragraphs in the new "Handbook," which was now in the hands of all members, relative to untuned proofs, and the form of licence for the reproduction of photographs, also further instructions in connection with the registration of photographs.

The Chairman also intimated to the members that a sheet almanac was being prepared giving the particulars of the Assistants' Scheme, etc., and he trusted that the members would have these posted up in some conspicuous place in their workrooms. He also hoped they would endeavour to make the scheme a success by encouraging their assistants to go in for the certificates, and that in applying for new assistants they would intimate that preference would be given to applicants holding P.P.A. certificates.

Some discussion followed on various points, and it was explained by the Chairman that the Committee had decided that in its present form it should be tried for a year, and that if any weaknesses were brought to light they would be then rectified. They were extremely anxious to establish a system which would be acceptable to both employers and assistants, otherwise it would not be practical. He would be willing to accept suggestions from any quarter.

The Chairman, in reply to Mr. Frank Turner, said the application forms would be ready in a few days.

The Assistant Secretary notified the result of the canvass of the members for the suggested Benevolent Fund up to the present.

Mr. Lang Sims drew attention to the subject mooted in the current number of the BRITISH JOURNAL OF PHOTOGRAPHY on the Shop Hours Bill.

Mr. P. Lankester drew attention to the large business which was done by stationers, etc., in picture postcards. He thought that photographers should endeavour to keep as much of this trade as possible in their own hands. He found that the sale of these cards led frequently to more important business in other directions. He was of opinion that photographers ought to do their own cards from their own negatives. By taking advantage of times when other business was slack, photographers in provincial towns should be able to place themselves in a more advantageous position than the stationers could both with regard to variety and quality.

Mr. L. Sims said that of course provincial photographers are different in this respect from town photographers, who have no views to take that would be worth anything as views. In reply a member stated that there was a demand for views of the most ordinary streets possessing no pictorial characteristics.

Mr. Lang Sims proposed, and Mr. M. Jacolette seconded, that the Committee discuss the question of holding a social evening at an early date.

Previous to the members' meeting a meeting of the General Committee was held. Present: Messrs. Alfred Ellis, Martin Jacolette, F. A. Bridge, S. H. Fry, H. Edmonds Hull, A. Mackie, D. Prodger, Edgar Scamell, Lang Sims, R. Fellows Willson, Wm. Grove, Wm. Gill (Colchester), P. Lankester (Tunbridge Wells), and H. C. Spink (Brighton); Mr. Alfred Ellis (Past President) in the chair.

The minutes of the previous Committee meeting, held on December 9, were read and confirmed.

The Assistant Secretary announced that the new "Handbook" for 1905 had been issued to the members, who now number 539. The draft forms of application, etc., for the assistants' examination were in hand.

It was decided, in order to bring the scheme under the direct notice of assistants, that an advertisement be inserted in the BRITISH JOURNAL OF PHOTOGRAPHY. It was thought the advertisement would serve the purpose of bringing the Association to the notice of the photographers and their assistants.

Mr. S. H. Fry again suggested the advisability of arriving at a decision regarding the method by which the Association could continue to retain the interest of assistants when they had obtained certificates by making them Associates, or in some way affiliating them to the Association. He was very anxious to see this suggestion carried through, and in this manner obtain the good-will and interest of the assistants in the Association.

The Chairman said he was afraid the matter could only be dealt with at a general meeting, and suggested that Mr. Fry should give formal notice of his suggestion and bring it forward at the next annual general meeting. He was quite in sympathy with the subject, but it was really outside the scope of the Association as at present organised.

On the proposal of Mr. Fry, seconded by Mr. Bridge, it was decided that the Committee should take the matter into consideration at their next meeting.

The Assistant Secretary announced that as a result of the plebiscite of the members as to the suggestion to form a Benevolent Society, he had received but thirty-two replies, seventeen in the affirmative with promises in the aggregate of about £13, the remaining fifteen being in the negative.

The Committee then constituted itself a Board of Arbitration to consider the case of Senior and Co. v. French and Co., which had been referred to them for settlement by mutual agreement.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MEETING held January 12. Mr. T. K. Grant in the chair.

Mr. P. R. Salmon, Editor "The Photographic News," read a paper entitled, "Woman, Her Face and Figure," illustrated with a selection of slides of high technical and artistic excellence.

The first section of paper dealt with the various types of female beauty, the second with a comparison between figures from certain well-known paintings and life models posed in the same attitudes, following which were life studies of Mr. Salmon's own composition. The comparison between the figure as painted and the figure from life explained the reason why artists required more than one model from which to build up the perfect whole, and also to show why photography of the nude must fail in rendering an ideal figure.

The Chairman said that Mr. Salmon had treated his subject throughout in a thoroughly masterly manner, and given the members ample food for discussion. In his opinion, the most successful pictures were those of Mr. Salmon's own composition.

Mr. Furley Lewis pointed out that the pictures copied were painted by Continental artists, and that the Continental type was of a more robust build.

Mr. Brown and Mr. H. W. Bennett were of opinion that Mr. Salmon's own compositions were the best, the imitations of the paintings proving nothing, except, perhaps, failure.

Mr. W. J. Kindon said such a comparison of figures must fail, painters building up their figures from various models, so that pictures from a single figure must suffer by comparison.

Mr. Hector Maclean said that each woman had only a modicum of beauty of figure, and was never perfect. He thought that lantern slides were the worst possible means of illustrating such a lecture; prints would have been far better.

Mr. Tespe said that the colouring of the background, etc., in a painting had much to do with the perfect rendering of the figure, emphasising certain points and accentuating them. These effects were entirely lost in a photographic reproduction, and gave a false rendering. Unless colour-sensitive plates, with a selective light filter, be used, photography cannot give true tone values.

Mr. Drage said Mr. Salmon's own compositions gave all the beauty of lines and curves, but they lacked the flesh texture; artists combined the two, and obtained a better rendering.

Mr. Salmon, in response to vote of thanks, expressed himself gratified with the reception of his paper.

ULSTER AMATEUR PHOTOGRAPHIC SOCIETY.

JANUARY 9. At the twentieth annual meeting held at the Museum, College Square, North Belfast, the gold medal presented by the Lord Mayor was awarded to Mr. D. W. Elliott. Mr. Alfred Werner, F.R.P.S., who judged the prints, placed Mr. B. J. Anderson second, Mr. L. B. Bagot third, and highly commended Mr. Hugh Cochrane, junior. The following officers were elected for 1905:—

President, D. Elliott, B.A., T.C.D.; committee, Miss W. Haslett, Miss E. Haslett, H. Struver, S. W. Allworthy, M.D., M.A., Hugh Hill, Wm. McLean, J. Campbell Carson, L. B. Bagot, A.M.Inst.C.E.; hon. treasurer, C. Mitford Martin; hon. librarian and hon. lanternist, Hugh Cochrane, junior; hon. secretaries, Thomas N. Murray and J. B. Anderson.

Mr. S. K. Kirker then gave an interesting lecture on "A Trip to the Canary Islands and Madeira," illustrated with about ninety slides taken from his own negatives.

SCOTTISH PHOTOGRAPHIC FEDERATION.

It was a happy thought of the originators of the S.P.F. that the annual general meeting should be held jointly with the opening of the

Scottish National Salon. Delegates were present from twenty-four societies, and a number of associates were also present. Mr. Henry Coates, president, occupied the chair. The annual report of the secretary (Mr. John B. MacLachlan) showed a steady growth on the part of the Federation from twenty-three at last annual meeting to thirty-two at the present, and incidentally mentioned that another two had already federated this year. The lectures, portfolio, slides, etc., circulated by the Federation had been largely taken advantage of; the lecturers and demonstrators had been kept very active. "The Blue Book," the year book of the Federation, and also the monthly journal, "The Secretary's Letter," had been heartily welcomed by the societies and associates. The treasurer (Mr. Archibald Campbell) reported a balance of £29, as compared with £17 at last annual meeting. Both reports were unanimously adopted. Office-bearers for the season were elected as follows:—President, G. D. Macdougald, Dundee and East of Scotland; vice-presidents, J. W. Eadie, Monklands, and D. Horn, Glasgow Southern; secretary, John B. MacLachlan, Blairgowrie; treasurer, Archibald Campbell, Stewart Terrace, Barnhill, Broughty Ferry; auditors, J. Murdoch, C.A., and R. C. Thomson. Council (after a vote)—Henry Coates, Perthshire Society of Natural Science; W. A. Frame, Glasgow Southern; R. Milne, Paisley Philosophical Institution; D. Dunlop, Motherwell; S. Stewart, Kirkcaldy; V. C. Baird, Dundee and East of Scotland; W. D. Boyd, Greenock; E. D. Wilmot, Edinburgh University; James Johnstone, Stirling.

It was decided that the next annual meeting be held in Dundee, and that the third Scottish National Salon be held at the same time and place. Power was given the Council to alter the date from February if found necessary. The annual excursion was also discussed and remitted to the Council. Mr. S. Stewart was unanimously re-appointed portfolio secretary. The secretary was instructed to exercise all diligence in the publication of "The Blue Book" for 1905.

PHOTO ART CLUB, ABERDEEN.

UNDER the auspices of the Photo Art Club a lecture was delivered by Mr. G. L. Smith, entitled "Recent Advances in Photography," last week. The lecturer referred to the rapid progress which photography had made during recent years. In speaking of portrait photography, he said the improvement had not been so marked. Some of the best work of the Daguerreotype and wet collodion days, would compare favourably with the average portrait of our own day. Landscape photography had, he said, undergone a species of evolution. First, we had the picture which aimed at microscope detail in every part, then came what was termed the "fuzzygraph," which name described it. Modern landscape had struck the happy medium, suppressing detail only in some minor parts, that the principal object and aim of the picture might at once be seen and understood. In this connection Mr. Smith spoke of the perfection of the modern camera for landscape work, compared with the crude, clumsy, and inferior article of earlier days. He explained the use photography was being put to in surveying, and of the utility of photographs taken from a height, by means of kites and balloons for topographical survey purposes, and in times of war. Perhaps the most interesting part of Mr. Smith's lecture was his description of the making of a star-chart, and of the great use photography was being put to in astronomical research. He said that in observatories all over the world a great combined scheme for the photographic mapping of the heavens had been in progress for years, and that tens of thousands of photographs would be included in the completed result. He would pass, he said, from recent advances of photography in the infinitely great, and speak of its explorations in the infinitely little. Here the lecturer gave a brief and interesting account of the methods and aims of photo-micrography.

In concluding, reference was made to colour photography, and a description given of the two processes which had produced anything

like successful results, namely the "three colour" and "Lippman's" process. The lecture, which was one of the most interesting of the session, was listened to with great attention throughout. The subject of the fortnightly competition was a "flashlight" print. The chairman read the criticisms by the judges, Mr. Findlay and Mr. David, and by the repeated applause their careful adjudication seemed to give great satisfaction. The successful competitors were, in order of merit: Mr. Jarvis Mr. Stephen, and Miss Dalgety. Mr. Stephen, the lanternist, with his assistant, Mr. Bow, showed a number of exceptionally good slides, by members of the club.

CROYDON CAMERA CLUB.

JANUARY 11.—"The Absorption of Light," by Mr. C. E. Kenneth Mees, formed one of the most instructive and interesting papers read before the members this session. Beyond a few simple algebraic equations, mathematics, for once, were left severely alone, and to the majority the lecture lost nothing in consequence. Mr. Mees had brought his modified form of the Hüfner spectrophotometer, and his lucid description of this complicated instrument was little short of masterly. Employed in conjunction with a powerful limelight, the spectrum was thrown on the screen, and a number of striking experiments were carried out. Although the lecturer did not say so, so far as recollection goes, this was the first time an absorption photometer had been used for screen projection, and no general audience had hitherto seen the actual "reading" of a plate density. After an incidental reference to three exceedingly important optical subjects—viz., the theory of lenses, the measurement of light, or photometry, and the absorption of light—all scantily treated of in English text books, though adequately in German treatises—Mr. Mees pointed out that there were two kinds of instruments which were termed photometers; one, an instrument designed for measuring the relative intensity of two light sources, the other designed for measuring the amount of light absorbed by any medium. The latter, he said, might more fittingly be termed an absorptionmeter.

Mr. Mees next dealt with Messrs. Hurter and Driffeld's work, and by means of simple blackboard illustrations showed that the "density" of a plate equals \log of opacity; the density, in all cases, being the weight or mass of silver present per unit area. The question of colour was then entered into, and shown to be correlated with wave length, different portions of the spectrum being identified by their respective wave lengths; for his own photographic work he generally employed the bright green portion. The varied absorbing powers of the following substances were, among others, next shown on the screen. Bichromate of potash solution transmitted red, yellow, and green; photographic ruby glass transmitted red, and a perceptible amount of blue; a "Geka" filter No. 3 passed red only: phenolphthaleine, on the addition of an alkali the solution turned to the familiar pink, and a gap in the green of the spectrum shot into position; by neutralising with acid the green was restored, affording a pretty experiment. Mr. Mees then passed on to a consideration of gas absorptions, and clearly explained Fraunhofer's lines, and the principles underlying them, concluding with a reference to a recent controversy which had taken place amongst the members as to whether the position of a light filter (other conditions remaining the same) affected exposure. He was definitely of opinion it did not.

In the discussion which followed, Mr. E. A. Salt inquired if Mr. Mees had made any experiments as to the absorberency of the ultra-violet by modern optical glass. Mr. Mees replied, this no doubt was appreciable, he had made no direct experiments, but under certain conditions thought 50 per cent. might be absorbed.

Mr. A. J. Newton mentioned that when dealing with wet plates, which were chiefly sensitive to the ultra-violet, the stopping powers of some of the modern lenses to this region of the spectrum was a very serious factor. With one of the most recent anastigmat process lenses sent to him to test, the requisite exposure, aperture for aper-

ture, was found to be thirty minutes, as against ten minutes when an ordinary type of R.R. was employed. He remembered in one case a whole battery of expensive anastigmats were laid on the shelf, cheap French R.R.s taking their place for this very reason. With the modern dry plate, owing to its vastly increased sensitiveness to other portions of the spectrum, the difference might not be appreciable.

Mr. A. E. Isaac differed from Mr. Mees's conclusion in respect of the position of a light filter, he believed the intensity of the light influenced the absorption curve. When in the diaphragm slot, or adjacent to the lens, the light intensity would be greater than if the filter were in the focal plane, and in the first place more blue would be forced through.

Mr. J. M. Sellors said he found that dyed-film filters, placed close to the focal plane, gave better definition than in alternative positions.

Mr. Mees said this merely proved the filter was of inferior quality: for the finest definition its glass supports must be optically worked, then its position was unimportant.

Mr. Newton did not agree. Given a perfectly true surface it was a matter of extreme difficulty to coat it with an absolutely even film of stained gelatine. Should this be uneven, definition would be impaired, but the defect would show least, if the filter were in position immediately in front of the plate.

SOUTHAMPTON CAMERA CLUB.

JANUARY 16.—Mr. C. H. Hewitt lectured on "Gum Printing." He dealt very exhaustively with the theory and material of the print production, setting out from the inception thereof by Mr. Poncey and pointing out by the way that it was claimed on behalf of the inventor that sufficient credit had not been given him for his work. After detailing the history of the process, the values of every class of paper in general use by prominent workers, the exact relation of the apparatus—shown by the lecturer—to the perfecting of the print, and the combination of pigment and medium with the necessary sensitising process; the lecturer proceeded to actual demonstration of the art. The manipulation of the whole process was accomplished, the development of the single coat print being followed by that of the built-up production. A very hearty vote of thanks was accorded him at the instance of Mr. G. T. Vivian, who presided.

A MEETING of the newly-formed Photographic Society of Cromer was held at Mr. Jessop's, High Street, on January 12, when Mr. D. Dawson was in the chair, and those present included Messrs. Barritt, Jessop, Samuels, Kirby, Battson, Munday, Goodyear, etc. It was decided that the Society should meet on the first and third Mondays in each month, while a proposition that the rules suggested by the committee should be adopted was also agreed to. The first meeting of the Society will be held on the first Monday in February. An interesting hour was devoted to the inspection of a number of photographs shown by the members.

A WELL-ATTENDED meeting was held in the Central Hall of the Church Institute last week to inaugurate the formation of the Kettering Camera Club. Mr. J. A. Gotch, J.P., F.S.A., occupied the chair, and in opening the proceedings said that he looked upon the art of photography as more adapted for scientific than artistic purposes, the chief function being to obtain records. Proceeding to point out the benefit of the League, Mr. Gotch said the advantages to be derived were many and various, the first being to associate its members for mutual assistance in photographic matters and social intercourse as a means of instruction, demonstrations, lectures, competitions and organised photographic excursions, and he was firmly of opinion that a camera club was possible, providing it was supported loyally by all interested. The rules were submitted by the secretary, Mr. E. Claypole, who said that Lord Lilford had kindly promised to become a patron of the club. Views were afterwards shown.

Commercial & Legal Intelligence

MIDLAND Counties Photo Company, Ltd.—A debenture for £150, dated December 10, 1904, charged on the company's general assets, has been registered. Holder -T. Sadler, 11, Nelson Street, Sunderland.

UNI-BIFOCAL COMPANY, LTD.—This company has been registered with a capital of £3,000 in £1 shares. Object: To carry on the business of opticians, wholesale, and retail manufacturers of photographic and projection apparatus, mathematical and scientific instruments and appliances, etc. No initial public issue. The signatories are to appoint the first directors. Qualification (except nominees of vendor or of any subsidiary or allied company), £100. Remuneration fixed by the company.

CLAIM for a Bioscope.—At the Greenwich County Court on Friday last, Walter Marchant, trading at Brattenham Road, Walthamstow; as Charles Ross, sued Matthew Brown, of Knowles Hill Crescent, Lewisham, for the recovery of a bioscope, films, etc., and for damage done to films. Defendant hired the machine and films to tour with, but paid nothing, and refused to return it. He had, however, sent back some films, which were now useless. His Honour gave judgment for plaintiff for £49 10s., to be reduced to £21 if the bioscope and films were returned.

An extraordinary general meeting of the Lumière North American Co., Ltd., was held on Monday at the registered office of the Company, 4, Bloomsbury Street, W.C., for the purpose of confirming a resolution passed at the extraordinary general meeting of the company on December 14 last, respecting the amendment of the articles of association regulating the directors' remuneration, directors' out-of-pocket expenses in attending meetings, and other matters. The notice convening the meeting having been read, the resolution of the general meeting was confirmed.

DETAINED Photographs.—At Barry on Tuesday Charles Pennell sued W. F. Jones, of King's Road, Cardiff, trading as the Provincial Portrait Company, for 25s., or the return of photographs sent him for framing. Mr. F. P. Jones-Lloyd appeared for the plaintiff. Judge Owen: Here is a letter from the defendant:—"We admit non-deliverance of photo frame owing to legal dispute." (Laughter.) Plaintiff said he had sent the defendant two photographs to be framed, and had not received them back. Defendant did not appear, and judgment was eventually given for the amount claimed, with costs, the amount to be reduced to 1s. if the photographs were returned.

A PICTURE Postcard Dispute.—At the City of London Court on January 9, in the case of Gale and Polden, Ltd., v. Clark and Misson, the plaintiffs; 2, Amen Corner, sued the defendants stationers, Gravesend, for £15 18s., the price of picture postcards supplied. "Mr. F. W. Hill, solicitor, represented the plaintiffs, and Mr. Percival Hughes was counsel for the defendants. Mr. Tomlin, traveller in the employment of the plaintiffs, said he obtained an order from the defendants for 1,000 packets of picture postcards at 3½d. a packet. There had been some previous negotiations with the defendant, Mr. Misson, who was told that it he cared to give an order for 1,000 postcards, he would have certain rights over other customers. He (the witness) was told to call later on, and did so, then receiving the order from an assistant. Nothing was said at the time about the cards being supplied upon sale or return. Mr. T. H. Misson said it was mentioned that, if he gave an order for 1,000, the cards would be on sale or return. On these terms the order was eventually given. They returned the cards left, and paid into Court the amount due for the cards sold. The Registrar was of opinion that the defendants had given an order for cards upon sale or return. Judgment was returned in their favour beyond the money paid into Court.

At Clerkenwell County Court, last week, Joseph Chanot, violin maker, of Wardour Street, was sued by the proprietor of "The Gentleman's Journal" for £4 4s. This was for taking photographs and making blocks for defendant's shop window, which appeared with an article in "The Gentleman's Journal." Defendant said the photograph had been touched up, and in this process the fiddles had lost their character. They looked like guitars. (Laughter.) Judge Edge (examining the photograph): I don't think anyone would suppose the instruments to be guitars, but the one at the end seems to have grown into a 'cello or double bass. (Laughter.) Plaintiff's representative: We did not make an art photograph. Judge Edge: Of course not. But he says you made the fiddles too fat. (Laughter.) A verdict was given in plaintiff's favour.

EMBEZZLEMENT.—Frederick Headley, of the Waverley Hotel, a traveller, was charged at the Plymouth Police-court on remand with embezzling the sum of £2 1s., the moneys of his master, Maurice Isidor Horwich, of the Modern Art Company, on December 24. Mr. S. Carlile Davis appeared for the prosecution, and intimated that he would confine his attention to one item of 7s. 6d., which accused obtained from Henry Sargaret, of the Caprera Hotel. Prosecutor did not press the charge, and asked the Bench to deal leniently with defendant. Prosecutor said the firm were photograph enlargers and picture frame manufacturers. Accused had no authority to deliver goods or collect money. He had not accounted for the 7s. 6d., which he had received from Mr. Sargaret. Prosecutor, through Mr. Davis, said the firm knew that defendant had a delicate wife, and as he had always been a good servant, they hoped the most lenient sentence would be passed. It was probable, if accused was not convicted, that he would be taken back into the firm's employ. Prisoner pleaded guilty, and was bound over in the sum of £5 to come up for judgment if called upon within six months.

SENIOR AND Co. v. French and Co.—This case was submitted to the arbitration of the Committee of the Professional Photographers' Association on Friday, 13th inst., by mutual agreement of the parties. Messrs. Senior and Co., of Bristol, are collotypers and printers of postcards, Messrs. French and Co. are photographers at Wallington, Surrey. About October last year, Messrs. French sent some negatives to Messrs. Senior from which to print postcards, and the results were so satisfactory that ten more negatives were sent, and subsequently another. The postcards were delivered in due course, and were immediately returned as not being equal to those previously made. One objection to them being partly on account of their being printed in an ink of different colour; a further objection to one particular set being that the title was wrongly spelled, and in another set that the spire of a church had been altered in the blocking out. A statement of the facts of the case which had been adopted by both parties was read, and a number of specimens were submitted to the inspection of the Committee, their unanimous decision being (1) that the second order was not equal to the first in quality; (2) that Messrs. French were not justified in returning the whole batch; (3) that the justice of the case would be met by Messrs. French retaining possession of the cards and paying the amount of the account, less 25 per cent. It must be explained that Messrs. Senior had not included in their formal statement of account the two subjects to which particular objection had been made.

WE understand on excellent authority that the Linked Ring have obtained a lease of the gallery of the Royal Society of Painters in Water Colours at 51, Pall Mall East for their future exhibitions. This gallery, it will be remembered, was for many years the home of the exhibitions of the old Photographic Society of Great Britain, now the R.P.S.

News and Notes.

THE Melita Studio has been opened at 211, Clapham Road, London, S.W., as a branch of the Regent Street studio of Mr. John Mallia, late of Malta.

A LECTURE on "Rising to the Occasion," was delivered before the Devonport Camera Club on January 10 by Mr. W. D. Welford, by whom also a demonstration of the carbon process was given.

WHEN leaving Sydney for America, Paderewski is said to have ordered 10,000 large panel photographs of himself for sale during his American tour, the largest order of the kind ever known in Sydney.

PHYSIOTYPE is a printing process now being placed on the market by Messrs. Barclay and Sons, 95, Farringdon Street, London, E.C. It is intended for the copying of ferns, lace, etc., and development is stated to be done by means of a powder.

A VERY sad loss has been sustained by Mr. W. Mottershaw, of the Sheffield Photo Company, and his family in the death of his second son, Mr. J. A. Mottershaw, who was only twenty-one years of age, and who passed away after suffering very severely during the last couple of months.

THE Cardiff Windsor Amateur Photographic Exhibition, the entries for which close on Sunday next (we thought we had heard of a Welsh revival!), includes a number of open classes. One is for photographic postcards, and in others prizes are offered by several of the large firms in the trade.

THE 1905 Kodak Competition.—The full text of the competition announced last week has now been published by Kodak, Ltd., and is obtainable from 57-61, Clerkenwell Road, London, E.C. There will be three open classes, and three for novices, i.e., for those who have never been awarded a prize in a photographic competition. Prizes vary from £30 to £1, and are distributed so that the total £400 will be divided amongst eighty of the competitors. Among the regulations of the competition are the following:—All pictures sent in to the competition must be from negatives made with a Kodak on Kodak N.C. Film, and must be printed or enlarged on one of the following printing papers: Solio, Self-toning Solio, Kodak C.C. Paper, Self-toning Aristo, Kodak Platinum Paper, Dekko, or one of the brands of Kodak Bromide papers. Prints only are to be sent in; not negatives. Prints must be mounted but not framed. The title of the picture, with the name and address of the competitor, class entered for, and the name of the printing paper used for the pictures, must be legibly written on the back of the mount. The film must have been exposed by the competitor, but it is not necessary that competitors finish their own pictures. No competitor will be awarded more than one prize in a class. Not more than one prize will be awarded to prints from one negative. Contact prints from the same negative cannot be entered in two classes. All competing prints are to become the property of the Eastman Kodak Company, except the non-winning enlargements (Class "C"), which will be returned at owner's risk and expense upon request. The negatives from which the prize-winning prints and enlargements are made to become the property of the Eastman Kodak Company. Entries for this competition will be received up to the last day of September, 1905, and should be addressed "Kodak Competition Department," Kodak, Ltd., 57-61, Clerkenwell Road, London, E. Continental exhibitors can arrange to have their prints forwarded direct and free of charge from any of our foreign branches. Detailed information on this point may be had by addressing Kodak, Limited, at the above address.

Correspondence.

POSTCARDS AND COPYRIGHT IN GERMANY.

To the Editors.

Gentlemen,—Referring to article "Week in History," appearing on page 4 of January 6 issue, and paragraph headed "Legalised Piracy," a case was fought, some little time back in the German Courts, under the auspices of the Photographic Copyright Union, on behalf of a member whose copyright photographs had been reproduced on postcards in Germany, with the result that the case was decided against them in the first Court, and although an appeal to the Higher Court was made against this decision, the case was lost on the grounds that a postcard was a "manufactured article."—Yours faithfully,

HENRY GOWER, Secretary.
Photographic Copyright Union.

London, January 9, 1905.

THE WEEK IN HISTORY.

To the Editors.

Gentlemen,—I am very surprised that among the anniversaries recorded by "Historicus," in the "B. J." for the 13th inst., no mention is made of the first publication of the Daguerreotype process which falls in the present week. Such a fundamental occasion as this ought surely not to have been overlooked by a writer, and it is inexcusable in one who claims even a superficial acquaintance with the past history of photography. I would ask "Historicus" to turn to the article on "Photogenic Drawings," in the "Penny Encyclopædia," published by Charles Knight in 1840, in which appears the following:—"Such apparatus is named after its inventor, the Daguerreotype, and the process itself, either photogeny, photography, or heliography (sun drawing). The invention was first formally communicated to the public by M. Arago, who read an account of the Daguerreotype before the Academy of Sciences, January 17, 1839. From that moment Daguerre (who was afterwards rewarded a pension by the Government) and his invention engrossed general attention." The notes by "Historicus" promise to interest a number who, like myself, do not limit their interest to the present day; but a gross omission, such as the one I point out, is calculated to irritate the reader.—Yours truly,

F. J. T.

January 14, 1905.

[Our correspondent is asked to moderate his anger until he has read the paragraph in "The Week in History" on another page, in which reply is made to him.—Eds. B. J. P.]

FOX TALBOT AND DEVELOPMENT.

To the Editors.

Gentlemen,—Your note, headed "Anniversaries," in last week's Journal, states that Fox Talbot "borrowed the idea of development from Daguerre, and possibly also, as there is evidence to show, from the Rev. J. B. Reade." In the case of Daguerre was not the development of the latent image an accidental "discovery"? The silver plate was not purposely exposed to the fumes of mercury, and in Talbot's case the use of a solution of nut-galls was also accidental if the published statement to that effect is correct.

I shall feel obliged if you will state what the evidence of Talbot's "borrowing" is. It is true that in 1837 Reade used gallic acid to develop negatives, but in his own words the discovery of "the master fact that the latent image which had been developed was the basis of photographic manipulation," was due to Talbot, and to him only.

In 1892 I was at some trouble to obtain the facts of this case, and if those facts are not as I have stated I shall be glad to receive correction.—Yours truly,

A. BROTHERS.

Handforth, Cheshire.

[We have often seen it stated that Daguerre's discovery of development was accidental, but on what grounds the statement is made we do not know. Our comment on the idea being borrowed by Talbot from Daguerre is based on the comments made by Talbot immediately after the publication of Daguerreotype. Speaking at the British Association at Birmingham, on August 24—Daguerre's process had been published on August 20—Talbot is reported, in "The Athenæum" (of August 31) to have said that "He had considered the possibility of applying a silver plate thus combined with iodine to the purpose of photogenic drawing, but he had laid it aside as insufficient for that purpose, on account of its sensitiveness appearing to be much inferior to that of paper spread with chloride of silver, and therefore in an equal time it takes a feebleness impression. Now, however, M. Daguerre has disclosed the remarkable fact that this feeble impression can be increased, brought out and strengthened, at a subsequent time, by exposing the plate to the vapour of mercury."

Again, in the action of Talbot v. Laroche, which took place in 1854, Talbot admitted in Court that "he first became acquainted with Mr. Reade's experiments when he published them in 1847, but he had heard a vague account in 1840 while speaking to a scientific friend. He thought that friend was Mr. Ross, an optician. What occurred was this: He was talking with his friend concerning photographic drawings and the means of making them more rapidly. Mr. Ross said that Mr. Reade had recommended infusion of galls." Report of the case in "The Photographic Journal," December 21, 1854. As Mr. Brothers says, Reade, on the other hand (according to the same report), "had on one occasion been called away, and at that time a piece of paper had only been a short time under the action of light, but when he came back he found an image upon it. This, however, did not give him the idea of a latent image, and he had not the slightest notion of it until he had learned it from Mr. Talbot. The Chief Justice: He was accidentally developing without knowing it by using gallic acid."

It may be assumed, we think, from these pieces of evidence that the idea of development came to Talbot from Daguerre, and that a stepping-stone to the development process, which he published in 1841, and in which he used gallic acid, was the account he had heard of Reade's use of gallic acid.—Eds. B. J. P.]

ABOLITION OF THE R.P.S. MEDAL.

To the Editors.

Gentlemen,—The announcement that the Council of the Royal Photographic Society have decided that no medal shall be offered in the Pictorial Section of the Exhibition to be held in 1905 must come somewhat as a shock to the ardent photographers all over the country, who, be they amateur or professional, have long regarded this coveted award as the *ultima Thule* of their endeavours in the world of photography. And is not this as it should be? Surely the five or six medals (intrinsically worth very little, but in all other respects worth a great deal) annually awarded in the Pictorial Section by the premier society should set the hallmark of excellence on the work of the recipients. Of course, the inevitable quibbler is always ready to hand every year to belittle the work of the judges and quarrel with the awards, but do we not find this individual in every phase of competitive endeavour where the awards to the many are regulated by the decision of one or two? Does he not attack the umpire at the cricket match and the referee at football, even though in many cases he himself has had a hand in choosing the arbiter? In the present case, let it not be overlooked that the judges at the R.P.S. Exhibition are chosen by the members themselves, and the

membership is composed of nearly one thousand interested photographers. Surely this is sufficient justification of the choice of judges, while a little investigation and thought will show that rather than sneer at the judges' awards a high tribute should be paid them for their perspicacity in distributing the medals to the right exhibitors, inasmuch as it is to be observed that in nearly every case for many years the R.P.S. medals have been awarded to workers who have proved themselves worthy of this distinction by the continued excellence of their work, displayed—sometimes for a period extending over many years—not only at provincial exhibitions, but also at the R.P.S. shows. I nevertheless agree with those in favour of the abolition of the medal, in that it has been considerably cheapened by the same individual winning the award on several occasions, and, although this may point to the continued excellence of that individual's work—a fact doubtless to be proud of—it cannot be denied that much more dignity and value would accrue to the award if the winning of it once were to be considered the final honour capable of being achieved by that particular photographer.

In any case I think the withdrawal of the R.P.S. medal will prove a grave mistake. It has been tried once before, some years ago, and it neither increased the number of pictures submitted nor raised the standard of the work one iota, and it is significant that it was not long before the Council thought fit to revive the custom, as they will undoubtedly do in the future.—Yours truly,

Gosport, January 14, 1905.

J. HALLIDAY WEST.

[Mr. West's letter opens a topic that is likely to be greatly discussed in photographic circles before the advent of the next R.P.S. Exhibition. We shall, of course, be pleased to publish the opinions of our readers interested in the medal question.—Eds. B.J.P.]

A NEW PRINTING PROCESS.

To the Editors.

Gentlemen,—I have been rather taken aback by the interest caused by the birth of my little bantling, as evidenced by the mass of correspondence I have received from all parts of the United Kingdom, on the subject of my new printing process. I find that my method of coating would be powerless to cope with the requirements, and I have had to order larger machines.

Meanwhile, I beg to ask my many correspondents, whilst thanking them for their kind and appreciative letters, to bear with me until I can reply to their many interesting questions, and get enough paper coated.—Yours sincerely,

HERBERT S. STARNES.

AMMONIA IN EMULSIONS: GAEDICKE'S PATENT.

To the Editors.

Gentlemen,—In reference to this patent, I should be glad if any of your emulsion-making readers would say whether in their opinion any novelty can be claimed for the method described, for personally I know that this method has been used in several works for some years.

It is a very common practice to ripen slow emulsions after washing by digestion with ammonia, soda, and other alkalies, and although some firms may send such alkaline emulsions direct to the coating machine, it has been my practice for many years to neutralise the free alkali before coating. This was done, not for the purpose of obtaining the many advantages mentioned in Gaedicke's patent, but simply because it is impossible to introduce chrome alum into an alkaline emulsion without producing fatal defects in the plates. Other emulsion makers have adopted the same method of working, and I do not know who first used this process.

This patent is of the same nature, so far as originality is concerned, as that which was taken out for the matting of emulsions by the addition of starch.

With regard to the ammonia remaining in the film, if the emulsion is not washed or neutralised after digestion, I should like to point out that I have coated such emulsions very often, but never found that the dried film had an alkaline reaction; on the contrary, the film was always acid to litmus paper. The explanation of this is probably that acid products are formed during the drying which more than neutralises the trace of ammonia remaining in the film, so that the ammonia exists in combination with an organic acid.—

Yours faithfully,
Mobberley, Cheshire.

C. F. S. ROTHWELL, F.C.S.

Answers to Correspondents.

*** All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

*** Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

*** Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

*** For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

G. H. Stainer, 2, North Parade, Taunton. Three Photographs of the Ven. W. H. Askwith.

A. Webster, Barnack, Stamford. Photograph of Uffington House Fire. Three Photographs of Ruins of the same.

J. Perkoff, 186, Commercial Road, London, E. Photograph of Louise Michel.

H. De Witt, "Balmain," Keymer, Sussex. Photograph of a Little Boy Feeding a Pig from a Bottle.

Barker's Photo Works, Albert Hall, Windermere. Photograph of Major and Mrs. Noble at Calgarth Hall, Windermere. Photograph of Maj.-Gen. Baden-Powell and Major Noble at same place.

E. M. Dickins, 7, Cambridge Avenue, Lincoln. Two Photographs of H. B. Dickins

PULLIGNY LENSES.—We are informed by a correspondent that Pulligny lenses can be obtained from M. H. Calmels, 150, Boulevard du Montparnasse, Paris, XIV.

REES AND CO.—Address, Harp Alley, Farringdon Street, London, E.C. It is against our rule to reply to inquiries by post.

D. (Gloucester).—The only registrations published are those made through our publishers.

P. L. AND CO.—We do not know the firm. Your best course is to address an inquiry to the local police. It is best in such transactions to make use of the deposit system, by which advertisers in our columns are able to protect themselves.

BOOKS ON STUDIO WORK.—Would you kindly tell me if there are any books published on posing, both groups and single figures, and also on lighting sitters in the studio. I shall be pleased to see an answer in your paper if you can manage it.—OPERATOR.

If you will turn to the reply to "C. C.," on page 39 of last week's issue of the BRITISH JOURNAL OF PHOTOGRAPHY, you will see that your question is answered.

POSITIVE FILMS.—I wish to make transparencies on ordinary "films" for stereo pictures, but I know of no films which are coated with "lantern" emulsion. How should I proceed to make contact transparencies with any ordinary "film" as to developer and exposure, etc.?—SUNDODGH.

Probably any firm making stiff celluloid films would coat some with lantern emulsion, but they can be obtained from Fitch and Co., Seldon House, Fulwood's Rents, High Holborn, W.C.

ADUROL.—In replying to a correspondent in last Friday's journal, you mention adurol as the developer which you prefer for

bromide paper. I should be much obliged if you would give what you have found a suitable formula.—C. E. F. N.

The developer we always use is:—Sodium sulphite, 4 oz.; potassium carbonate, 3 oz.; distilled water, 10 oz. Dissolve the carbonate first, then add the sulphite and stir till dissolved, and add adurol, $\frac{1}{2}$ oz. For use, dilute one part with seven parts of water, and add $\frac{1}{4}$ grain of potassium bromide to the ounce, though this last is not really necessary.

EQUIVALENT WEIGHTS.—Red tones on "C.C. matt paper," p. 29, B.J.P. for January 13. Will you kindly give me the formula in grains and ounces?—T. JONES.

It is very easy always to convert the metric measures into the English ones if the grammes are reckoned as grains and the cubic centimetres as minims. Still, the formula would read:—

Prepared chalk $\frac{1}{2}$ oz.

Water 20 oz.

Chloride of gold (1 per cent. solution)..... 96 minims.

OZOTYPE.—Can you tell me whether the ozotype process is difficult, and what are its essential features, and can the material be obtained commercially?—W. B.

The ozotype process is not a difficult one, and may be briefly described as follows: A well-sized paper is sensitised with bichromate of potash and a manganese salt, dried and exposed under a negative, when, of course, a visible image is obtained; this is then washed in water and dried, and is then soaked in a special bath with a piece of "pigment plaster" or special carbon tissue, and then squeezed together. The print is then developed in the ordinary way, and the image is found to be transferred to the unexposed carbon tissue. The materials can be obtained from the Ozotype Company, Kenash Town, N.W.

INSTRUCTION IN COLLOTYPE.—Would you kindly give me information on the following subjects?—(1) Are there any evening classes in London where colotype printing is taught? If so, could you give me any particulars regarding them? (2) What is the average wage of an improver to colotype printing? I would like to know the wage for one who has had five and a half years' experience in colotype printing.—TYRO (Leeds).

(1) The London County Council School of Photo-Engraving and Lithography, Bolt Court, Fleet Street, E.C., and the Photographic School, Regent Street Polytechnic, London, W. Write to the Principals for prospectuses and fees. (2) We believe an average wage for an improver-printer (i.e., a machine minder) is from 30s. to £2 a week.

NOTICE.

A number of "Answers to Correspondents" are crowded out of this issue, and will appear next week.

*** NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

Bold Advertisement. While we hold strongly the view that the best advertisement a photographer can display is a high standard of work, we would not, therefore, discourage the practice of organised publicity. Photographers' advertisements, whether in the press or on the hoardings, are too often wanting in the qualities which make them read and remembered. A vein of humour is the making of many an advertisement, and a hint may be taken from a photographer in an American city who displays from his establishment the legend, "Time is flying. You will never be so good looking again. Come in and be taken now."

* * *

In Memoriam. The phlegmatic temperament of the Anglo-Saxon does not make for hero-worship, and it will probably be many a long day before a photographic society in this country follows the example of the Deutsche Photographen-Verein, which has just fixed a memorial tablet on the house in Nordhausen, where formerly resided Ludwig Belitski, an honorary member of the association, whose death took place about two years ago. Indeed, if we are not mistaken, the only two memorials to British photographers are the Traill-Taylor Lectureship in honour of a former Editor of this journal, and the extension of the chancel of Lacock Church, in Wiltshire, which was undertaken some time ago as a memorial to Fox Talbot.

* * *

Action of Light on Uranium Solutions. A note recently published in the "Journal" of the Berlin Chemical Society may prove to have some application in the employment of uranium salts as the sensitive materials in photographic printing processes.

According to A. Bach, uranium acetate in solution is not reduced on exposure to sunlight unless carbon dioxide is present. In the absence of carbon dioxide, or if the gas is led through the solution in the dark, the reduction to uranous and uranic hydroxides was found not to take place, in opposition to the experience of Euler, who had noted the reduction both in the presence and absence of carbon dioxide. Herr Bach takes the view that impurities in one or other of the uranium salts may account for these contradictory results.

* * *

Photography and Public Characters.

We read that, before leaving Sydney, Paderewski ordered 10,000 large panel-size portraits of himself for sale and distribution during his American tour. This is a large order to give for one's own portrait, but doubtless it will prove remunerative from an advertising point of view. Some two or three decades ago, more than one photographic firm made reputations by the publication of the portraits of actresses as well as reaped a good harvest by the sale of the pictures. This class of business of late years, so far as the sale of the pictures is concerned, has been considerably discounted by the portraits that appear in the illustrated papers which are printed from high-class process blocks. It has justly been said that in years gone by some photographers' reputations were largely made by the theatrical profession. It now would almost appear that conditions are reversed, and that the reputations of not a few artistes, particularly of the "variety" stage, are largely due to photography, aided by retouching. The circulation of the portraits in the "illustrateds," and the exhibition of them in the shop windows, serving as an excellent advertisement. If one with the reputation of Paderewski finds it worth his while to order such a large number of his portraits as above stated, supposing the report to be correct, by way of advertising himself, one may fairly assume that the large circulation of minor celebrities' portraits would be highly beneficial to them.

* * *

Bank Note Forgeries.

A case of the forgery of Bank of England notes is now engaging the attention of the police authorities. In this instance it appears that photography has played no part. In most previous cases it has, or it has been alleged that it has. At first sight it would appear to be a very simple matter by photo-mechanical methods to produce spurious bank notes that would defy detection. But the thing is not so easy as it seems, as evidenced by the comparatively few attempts there have been to forge the notes. The main things the Bank authorities rely upon is the simplicity of the design and the water-mark of the paper. In some countries the engraving is of a very intricate character, and not easy of imitation. In Russia, colour-printing is now

adopted. But one would think that photography is now quite equal to these cases, and the spuriousness of the notes, even if the results were somewhat crude, and easily detected by experts, would not be so readily noticed by the general public, on whom they were foisted as plainer ones, particularly if they had not genuine notes at hand with which to compare them. It is difficult to carry in the mind the intricacies of a fine design, or the exact tint of any particular colour. With the simplicity of the design, and the water-mark, of the Bank of England note a spurious one is more easily detected by the general public than would be one with a more intricate design, particularly if colour were added to it. This, we believe, is why the Bank authorities have so long adhered to the present simple style of note.

Photographers' Benefit Association. During the past few months there has been considerable correspondence in our columns as to whether it is desirable to form a benevolent association amongst photographers: and, if so, how is it to be done, and who are the proper ones to take it up? Of the desirability of such an institution there is no question, provided it was founded on a firm basis, and it received the active and pecuniary support of those it was intended to benefit in time of need. Various suggestions have been made as to who are the proper ones to take the matter in hand, and amongst others the Professional Photographers' Association was named. This Association which numbers some five or six hundred members, is a very representative body, and the Committee took the matter into serious consideration. At their last meeting, the result of the plebiscite of the members as to the suggestion to form a benevolent society, the Assistant Secretary reported that he had received but thirty-two replies, seventeen in the affirmative, with promises in the aggregate of about £13, the remaining fifteen being in the negative (see page 54 of our last issue). The response may reasonably be taken as indicative of the attitude of the profession towards the formation of a photographers' benevolent society. It is quite possible that the fifteen members who replied in the negative, and possibly some who did not reply at all, had in mind the old Benevolent Association and the scant or non-support it received from those for whose benefit, in time of misfortune, it was founded. It is notorious that, although the subscription was quite a trifle a year, but very few employees subscribed to the fund, though not a few applied for assistance when they were overtaken by misfortune.

* * *

A Neglected Branch of Business.

At the last meeting of the Professional Photographers' Association one of the members called attention to the large business that was being done by stationers and the like in picture postcards, and suggested that photographers should keep this trade in their own hands as much as possible. This is a thing we have often advocated since the picture postcard became firmly established in this country. Many of the picture postcards published in provincial towns—particularly in small country towns—have been copied from local photographers' views, which they have issued of a larger size, and sold at a shilling and upwards each. Not unnaturally, the photographer, when he finds his work thus reproduced, feels aggrieved, but, after all, but a limited amount of sympathy can be extended to him, inasmuch as he might have prevented piracy, or have recovered substantial damages for it, had he taken the trouble to register the copyright in his work, which he could have done for a trifling sum. On the

other hand, one can have but little regard for stationers and others who annex what is—morally, at least—another man's property. It is not all photographers, however, who have ignored the picture postcard business, for we know that many have done a very remunerative trade with them by supplying them wholesale to the stationers, as well as by selling them retail themselves. A photographer is in a better position to supply picture cards at a low rate than are others, inasmuch as he produces the negatives, and can print them as bromides at a quick rate when he or his assistants have nothing else to do; or, failing that, he can send the negatives to a trade collotype printer. As a rule, however, unless very large numbers are required, he will find the bromide process the more economical, while the results will probably suit the public taste the best.

* * *

Impure Shellac.

The increased cost of genuine shellac, as we pointed out some time ago, has led to great adulterations being practised; in fact, to such an extent is sophistication done in some cases that the shellac becomes totally unsuitable for varnish making. This question came up in a paper recently read before the American section of the Society of Chemical Industry. The author, A. C. Langmuir, refers to the scandalous substitution of resin for shellac, the former being about one-fifteenth the cost of the latter. Mr. Langmuir gives a number of analytical methods for the detection and determination of resin. He adds two practical tests which may be applied to a suspected sample by those unprovided with the means of elaborate analysis. The first of these tests is based on the fact that the higher the percentage of resin the more bleaching solution of sodium hypochlorite is needed to decolorise the sample. An ounce of shellac is dissolved in sodium carbonate solution by heat—if there is 10 per cent. or more of resin its odour will be recognised—the solution allowed to stand for fifteen minutes, and decanted through a fine sieve. It is cooled to 105 deg. F. and solution of sodium hypochlorite of standard (decinormal) strength added until a cream colour is finally obtained. A pure shellac will require 150 to 175 c.c.s., but the amount may be as great as 250 or 300 c.c.s., if much resin is present. The sample is tested alongside one of known purity. In the second test the red-violet colour characteristic of resin is obtained by adding a drop of sulphuric acid to a solution of the shellac in acetic anhydride. One gramme of the sample is treated with acetic anhydride to obtain the resin in solution by careful warming. The bulk of the shellac is filtered off as a gelatinous mass. To the filtered liquid in a test-tube a couple of drops of strong sulphuric acid are added. Where the acid meets the liquid a coloration is produced, with so small a proportion of resin as 2 or 3 per cent.

PLATINUM TONING.

THE use of platinum for the toning of print-out papers cannot be said to have obtained the wide vogue prophesied for it at its inception. Like many another process, it suffered from the over-sanguine views of its supporters. It has been argued that a print toned with platinum must possess a high degree of permanency, a claim, it need hardly be said, which rests on a basis almost as unsubstantial as the still wilder statements to the effect that a platinotype print—because it consists of the noble metal—can be "toned" by various chemical mixtures without prejudice to its lasting character. In point of fact, the

toning with platinum of a printed-out image on collodion emulsion involves conditions which are in the direction of impermanency of the prints and this statement is still more applicable to the case of a gelatine print-out paper. It may be well to refer to one or two of the points wherein platinum toning chiefly differs from gold, in the hope that photographers will perceive the necessity of precautionary measures. Like gold chloride, the active toning agent potassium chloroplatinite, enters into reaction with soluble salts of silver—e.g., with the silver nitrate or silver citrate which are more or less completely removed from the print in the washing before toning. But, whereas gold chloride, like other chlorides, produces silver chloride, which is practically harmless, the chloroplatinite forms silver chloroplatinite, and this is a compound which will give rise to yellow stain if formed in the film even in minute quantities during, or after, toning. The access of actinic light to the prints during this operation is a predisposing cause of discoloration, and on this account greater care is necessary with platinum than with gold. A procedure often recommended in platinum toning is to immerse the prints without washing in a weak solution of common salt, a treatment which is advisable for the reason that it converts the whole of the soluble silver compounds into chloride of silver, and thus leaves the print in a state in which it cannot form silver chloroplatinite when it comes into the toning bath.

Then the platinum toning bath is acid, and that fact exposes the process to irregularities in two ways. In the first place, the speed of toning increases with the acidity of the bath, and if prints carry into a bath any considerable proportion of the free acid which many of them contain the speed of toning will be increased. That would not matter were the course of toning readily discernible, but in platinum toning it is rarely possible to watch the toning action, and it is necessary to give a fixed time in a bath of known composition. For this reason it is advisable to obtain the prints in a uniform state as regards acidity before they enter the toning bath, for which purpose a preliminary treatment in a solution containing salt and bicarbonate of soda is prescribed. The salt converts the soluble silver compounds into chloride of silver, and the bicarbonate neutralises any free acid. The second precaution which the acid toning bath renders necessary concerns the subsequent fixing. No traces even of acid must be carried by the prints into a plain fixing bath of hypo. If they are we have at once the proper conditions for decomposed hypo and decomposed hyposulphite of silver with their after effects in the form of yellowing of the prints. Hence steps must be taken, either in the shape of an intermediate alkaline bath or by the composition of the fixing bath, to guard against this acidification.

There is no difficulty in observing these conditions in the toning operations, but they represent additional precautions, and hence explain the comparatively slight extent to which platinum toning has come into use. If a neutral or alkaline bath could be found one great objection to the process would be removed, but though baths of this character have been put forward their toning action is extremely slow; in fact, no toning whatever takes place with some papers. Potassium oxalate and potassium chloroplatinite formed a bath of this kind some years ago, but it gave only warm brown tones on the paper for which it was intended, and was destitute of toning action on many other brands. An acid or acid salt appears to be a necessary auxiliary to the platinum toning of gelatine and collodion papers, but it is well to avoid the stronger acids, such as nitric and hydrochloric, and to choose in preference a weaker mineral or organic acid. Professor

Namias, after the examination of a number of platinum baths differing only in the acid used, concluded that oxalic acid was the least open to objection, and that phosphoric acid, often used to acidify the platinum bath, was to be avoided. But our experience and advice are that the formula is less important than the way it is used, and that complaints of the platinum bath are due to neglect of recognising the differences in manipulation which it requires.

FROZEN WATER PIPES.

THE recent frosts have caused serious inconvenience in the shape of frozen water pipes to many photographers. In nearly every case the trouble might have been avoided had a few timely precautions been taken. Serious as is the inconvenience of a frozen water supply, a still more serious one may follow when a thaw sets in, and burst pipes make themselves manifest. This latter may usually also be avoided by a timely precaution. If, when the pipes are found to be frozen, they are carefully examined throughout their length, the fracture will be discovered by a bulge in the pipe and ice protruding through it. Then the aid of the plumber should be sought at once. While the frost lasts there is little difficulty in obtaining the services of a plumber, but when a general thaw occurs it is not such an easy matter, and much damage may be caused by the escaping water. If the above precaution be neglected, and the burst is only found out by the escaping water, the supply should be cut off by plugging the outlet pipe from the cistern. If this cannot be readily done, the next best thing is to batter up the pipe with a hammer, a few inches in front of the fracture. This expedient will make a little more work for the plumber, but the cost of that, when the burst is in the house, is well saved by the avoidance of flooded premises, damaged carpets, furniture, and the like, to say nothing of saturated walls that may, possibly, take months to dry. If in a case such as that just cited, the supply of water can be cut off, the pipe may be temporarily repaired by the photographer himself, and still be useable. Here is the method. First the pipes should be pulled well away from the wall; then, with a couple of hammers, using one as an anvil, the fracture is closed as neatly as possible. Next, a plaster, spread on linen, of equal parts of white lead and putty, is applied, and bound tightly round several times with strong broad tape. A repair thus made, if well done, will last for many months without leakage. An old aphorism runs, "Prevention is better than cure," and severe as has been the weather we have had, still more severe may follow, and it will not be too late for those who, up to the present, have suffered no inconvenience to adopt precautions against the trouble it may bring. One good precaution is to leave the water just dribbling at all the taps, particularly at nights. This the water companies will object to, if they are aware of it, and if the water is paid for by meter it adds slightly to the water bill. All outside or much exposed pipes should be protected by binding them round with hay or straw bands. A thick hair felt is now supplied by most ironmongers, specially made for the protection of water pipes against frost, and it is very cheap and is excellent for the purpose. When the main supply pipes are laid near the surface of the ground, as they frequently are, they may possibly freeze during a long and severe frost. The best way of protecting them is by spreading over the ground above them six inches or so of good stable manure. Exceedingly simple precautions, if taken in time, will avoid the inconvenience and discomfort of frozen water pipes, but they are too often neglected until too late.

THE FOCAL PLANE SHUTTER.

II.

In continuation of the previous article on this subject (THE BRITISH JOURNAL OF PHOTOGRAPHY, January 20), it will be well to refer to a paper contributed to a recent issue of "Das Atelier," by W. Schmidt, in which is examined the effect on efficiency and rapidity, when the focal-plane shutter is worked, not in its normal position, closely adjacent to the plate, but in a plane considerably nearer the lens. The case is one of practical importance, inasmuch as it may arise when a back extension is employed with a focal-plane camera. It remains to be seen how far the calculations as to speed and exposure under these conditions are borne out in actual work, but the notes of Herr Schmidt should appeal to users of focal-plane shutters as drawing attention to factors which are largely disregarded. Calling the time occupied by the slit in traversing the whole plate the "absolute rapidity," and the time during which the slit moves through a distance equal to its own breadth the "relative rapidity," the relation of the shutter when in its normal position close to the plate is shown in Fig. 1. Rays enter the camera in all directions through the diaphragm aperture b . They are limited by the diaphragm and by the slit. The latter is never in the ideal position of contact with the plate, but often .5 cm. away from it. For this reason the area $B C$, which receives the full action of the rays from the diaphragm, is bordered on either side by the bands $A B$ and $C D$, in which the light action falls off, this falling off depending on the diameter of the stop, the breadth of the slit, and the distance of the curtain from the plate. The action does take place to an extent sufficient to affect the efficiency of the shutter in practical work.

Distortion.

This commonly alleged defect of the focal-plane shutter is viewed more seriously by Herr Schmidt, who points the example of an exposure made from a train in rapid motion. If the slit of the shutter travels from top to bottom of the plate, the image will be sharp in all parts, but vertical lines will be rendered as leaning forwards, as the upper parts of the plate are exposed before the lower ones. The tilting of the vertical lines from this cause will increase with the rate of movement of the camera past them, assuming that the exposure is rapid enough to give a sharp image. Reference is made to the camera of Curt Bentzin, which employs a square focal-plane shutter, the position of which can be adjusted so that the slit runs parallel with the length of the moving object, its direction of movement being either that of the object or, better, the opposite.

The Position of the Shutter when Exposing.

In the case of a hand-camera it is obvious that any such special apparatus is unnecessary, as the camera itself can be held in the best position. W. Kilbey, in his "Advanced Hand Camera Work," draws attention to this precaution in the use of the focal-plane shutter, and directs that the camera should be turned into such a position "that the direction of the shutter is contrary to the movement of the image, or, in other words, in the same direction as the subject." In accordance with this rule and, presuming that the camera is built according to the usual type, with the slit of the shutter parallel to the longer edge of the plate, it is recommended by Kilbey that the camera be held in its normal position for diving or falling objects; upside down for high jumping or rising objects; and vertically for subjects which move practically at right angles to the axis of the lens.

The Slit Shutter Removed from the Plate.

The action of the slit (proceeds Schmidt) is modified if the camera be fitted with a rear extension, which sets back the plate and leaves the shutter about midway between it and the lens. The dotted portion of Fig. 1 shows the altered con-

ditions. P is the plate at the focus of the lens of approximately double focal length. From this it will be seen that the area fully illuminated by the diaphragm is contracted to $B_1 C_1$, and the side bands are as shown by $A_1 B_1$ and $C_1 D_1$. To ascer-

Fig. 1.

tain the relative rapidity at this double extension, it must first be found how many times the slit must move the distance of its own breadth to reach the point whereat no further light reaches the surface corresponding to it at the rear position. This number multiplied by the relative rapidity of the slit in position P gives this rapidity in position P_1 . In this method, which takes account of the total breadth of the area of diminished light action, a small error creeps in, as the intensity of the light at the time affects the action on these portions. In dull weather there may be no action, and so the breadth of the slit must be taken as less than the theoretical, and the rapidity becomes slightly greater.

Efficiency at Single and Double Extension.

The relative intensity of illumination at single and double focus is not so easily dealt with. In place of the unequally illuminated area at the double focus, the equally illuminated

Fig. 2.

Fig. 3.

Fig. 4.

one between B_1 and C_1 must be taken as the basis of calculation. This area is smaller than the original one, as the illuminations vary inversely as the areas, and as in each case the illuminated area is a rectangle of the same length, calculations can be based on the width of the slit. Perhaps the conditions can be more clearly expressed by means of an example. Let the breadth of the slit be 1 cm., and that of the surface illuminated under the altered conditions 4 cm.

Then the illuminations of the two surfaces are as 1:4. But the relative rapidities of the slit are different in the two cases, say 1-120th second in the normal position and 1-40th second in the position of double focus. Hence the more weakly illuminated area at the double focus is exposed for three times as long (1-40 : 1-120). Thus the plate at the double focus receives only three-quarters of the light obtained at the single or normal focus. As no exact mathematical treatment of the problem can be given, it may be noted by those who are interested in this method of approaching the subject that two cases must be distinguished: the first (Fig. 2), in which a crossing of the rays takes place before they reach the double focus, and secondly (Fig. 4), the case in which no crossing occurs. In the first case the width of the slit is larger, and in the second smaller, than half the diameter of the diaphragm. If $s = \frac{1}{2} b$ (Fig. 3), where s is the width of the slit and b the diameter of the stop, then the illuminations are the same in each case.

A Table for each Shutter.

The following table is drawn up on these lines. The relative

mm	2	4	6	9	12	15	20	25
40	$\frac{1}{1.25}$							
	$\frac{1}{24}$	$\frac{1}{24}$	$\frac{1}{23}$	$\frac{1}{22}$	$\frac{1}{22}$	$\frac{1}{21}$	$\frac{1}{20}$	$\frac{1}{19}$
	0.52	0.52	0.56	0.56	0.56	0.59	0.62	0.67
30	$\frac{1}{1.5}$							
	$\frac{1}{34}$	$\frac{1}{33}$	$\frac{1}{32}$	$\frac{1}{30}$	$\frac{1}{29}$	$\frac{1}{28}$	$\frac{1}{26}$	$\frac{1}{25}$
	0.52	0.52	0.56	0.59	0.59	0.62	0.67	0.71
20	$\frac{1}{2.0}$							
	$\frac{1}{48}$	$\frac{1}{45}$	$\frac{1}{43}$	$\frac{1}{41}$	$\frac{1}{38}$	$\frac{1}{36}$	$\frac{1}{33}$	$\frac{1}{31}$
	0.52	0.55	0.59	0.62	0.67	0.71	0.77	0.84
10	$\frac{1}{2.50}$							
	$\frac{1}{91}$	$\frac{1}{83}$	$\frac{1}{77}$	$\frac{1}{69}$	$\frac{1}{66}$	$\frac{1}{57}$	$\frac{1}{55}$	$\frac{1}{44}$
	0.56	0.59	0.67	0.71	0.77	0.91	1.06	0.91
5	$\frac{1}{2.60}$							
	$\frac{1}{167}$	$\frac{1}{143}$	$\frac{1}{125}$	$\frac{1}{105}$	$\frac{1}{91}$	$\frac{1}{80}$	$\frac{1}{67}$	$\frac{1}{57}$
	0.59	0.71	0.84	1.00	0.91	0.84	0.77	0.71
2	$\frac{1}{3.00}$							
	$\frac{1}{333}$	$\frac{1}{250}$	$\frac{1}{200}$	$\frac{1}{154}$	$\frac{1}{125}$	$\frac{1}{105}$	$\frac{1}{93}$	$\frac{1}{69}$
	0.77	1.00	0.84	0.71	0.67	0.62	0.59	0.59

speed of the slit at its different widths is taken as known, being obtained from the table of approximate speeds of the 9 by 12 cm. focal-plane shutter of Carl Zeiss. It should be

noted that these are the speeds at the lowest tension of spring; when working at the full tension they must be doubled. The table is arranged so that the widths of slit (in millimetres) fall in the left vertical column. The diameters of the diaphragms are given also in millimetres in the top horizontal column. By giving this dimension the table holds good for all focal lengths, assuming that the shutter is worked at a single and double focus. Opposite to each width of slit are three lines. The first, one number only, is the relative speed of the slit, and applicable to all diameters of stop. The second row gives the relative rapidity at the double focus for each diameter of stop, and in the third row is the relative illumination, taking that at the single focus as 1.

How to Use the Table.

A couple of examples will make the arrangement clearer. Working with a slit 20 mm. in width and with a stop of 12 mm. diameter, the relative rapidity of the slit is 1-50th second. Under 12 mm. in the top column is 1-38th second, the relative rapidity at the double focus, and underneath it again the number .67, indicating that the plate receives .67 of the light which would reach it were it immediately behind the shutter. Thus the plate altogether loses one-third of the light. To take another example: We wish to work at the double focus with a speed of 1-125th second. We find this, or the nearest number, in the middle columns opposite one or other of the slits. It will be found in the two bottom columns, giving us the choice of a 5 mm slit with 6 mm. stop, or 2 mm. slit with 12 mm. stop. We shall naturally choose the former, as we obtain greater depth of focus and there is not so much loss of illumination as in the second case.

Alternatives in Practice.

This last example shows the wide application of a table of this kind, and how it indicates the best course to pursue in practice. It may be well, therefore, to offer a few notes on it before concluding. If the figures which indicate the light illuminations be examined, it will be seen that in the three lower columns they rise to 1 and then fall again. They thus point out the advisability of working with the slit of width half the diameter of the stop. Under these conditions the relative rapidities at the single and double focus are in the simple ratio of 2 : 1. The table further shows how the relative rapidity at the double focus is depressed by the use of a large stop and by broadening the slit. On both of these grounds the photographer will most usually choose to obtain a certain speed in the way already indicated, as he thereby avoids the sacrifice of depth of focus and illumination. On these lines, one would use of the bottom row of speeds at the double focus only the first three, obtaining the slower ones with the wider slit in the row above. Of this latter series one would use only the first four, selecting speeds of 1-90th and less from the 10 mm. slit. The table also shows that as the width of the slit increases the diameter of the stop loses its influence on the speed, and that at last the relative speed at the double focus is very little less than that at the single position of the shutter.

A DISTRESSING CASE.—Walter John Newey, photographer, Lord Street, Wolverhampton, pleaded guilty to stealing a watch and chain, value 25s., the property of William Mogg, drayman, Tamworth, on January 6. Defendant was canvassing for orders, and appropriated the watch during the temporary absence of the occupant, and pledged it with a Tamworth pawnbroker. He was under the influence of drink at the time. Mr. J. A. Cotterell, solicitor, Wolverhampton, said defendant was well connected. He addressed the Bench in mitigation of punishment. A fine 40s., inclusive of costs, was imposed.

THE WEEK IN HISTORY.

Sulphite in the Developer.

LET everybody who uses a developer recall to mind the boon of cleanly working which was brought by Berkeley twenty-four years ago to-day. In *THE BRITISH JOURNAL OF PHOTOGRAPHY* for January 27, 1882, appears the paper on "Sulphite of Soda in the Developer" read by Mr. Herbert B. Berkeley before the (then) Photographic Society of Great Britain. A brief mention of sulphite had already appeared in an article on emulsions in the "Almanac" for that year, and the addition came as a relief from the plague of "yellow sickness" which afflicted gelatine negatives developed with pyrogalllic acid. Mr. Berkeley made up his pyro developer by first dissolving forty parts of crystallised sulphite of soda in water, a little short of one hundred parts. The solution was then nearly neutralised by addition of citric acid, ten parts of pyro added, and the whole made up to one hundred parts with water. The intention in adding the citric acid, wrote Berkeley, "is to neutralise the alkalinity of the sulphite, which, besides being itself an alkaline salt, commonly contains carbonate as an impurity, the crystallisation being very imperfectly carried out. The alkalinity might tend to the oxidation of the pyro and cause the solution to have less perfect keeping properties. Probably from this point of view it is a refinement of no great value. But we prefer to consider our pyro to be neutral. One slight objection to citric acid alone as a preservative of pyro was the necessity of allowing for the amount of citric acid present in each developer, and this, of course, varied with the quantity of pyro solution used."

It is curious to recollect that the predecessor of sulphite as an addition to the developer was the "hydrosulphite," or real "hyposulphite," which Messieurs Lumière have recently brought forward as a developer. A formula for pyro *plus* hydrosulphite was given in the *JOURNAL* by L. O. Sammann about five years before Berkeley's paper, and though it was noticed as being free from stain, this was not a quality in those last days of collodion to bring it into prominence.

Daguerreotype in Embryo.

Under the date of January 29, 1832, there is a letter of Nicéphore Niépce to Daguerre, an extract from which is notable in the voluminous correspondence between the two inventors, as it substantiates Daguerre's claim to be the originator of the process which bore his name. Wrote Niépce: "To the substances which resemble iodine in their action on silver you may add a decoction of thlaspi, vapour of phosphorus, and especially sulphides. It is principally to the presence of these latter that the results are due. . . . I am no longer using iodine in my experiments, except as a means of comparing the relative rapidity of my preparations." Most of Niépce's letters are collected in a book by Victor Fouque, a bookseller of Chalon-sur-Saône, published in 1867. The title is "La Vérité sur l'Invention de la Photographie. Nicéphore Niépce, sa vie, ses essais, ses travaux, d'après sa correspondance et autres documents inédits." The author's attitude is strongly pro-Niépce, but there seems no reason to doubt the authenticity of the letters which were published in 1867, after having lain in a granary for thirty years.

The Talbot Process.

On January 30, 1839, the first intimation (at any length) of Fox Talbot's process of "photogenic drawing" was made

to the Royal Society. It was a preliminary announcement and gave no particulars of the actual method employed. It is somewhat of a reflection on the Royal Society that the paper should have been read at all, as descriptions of secret processes are not accepted by scientific societies, the Royal Society least of all. In 1828 a very similar kind of note by Niépce on his process was offered to the Royal Society and declined; but no doubt it was understood that Fox Talbot's paper would be followed—as it was—by a disclosure of the process. The paper is entitled, "Some Account of the Art of Photogenic Drawing, or the Process by which Natural Objects may be made to delineate themselves without the Aid of the Artist's Pencil. By H. F. Talbot, F.R.S." It does not appear in the "Philosophical Transactions," but is abstracted on pages 120, 121 of the "Proceedings." The paper in full was printed in "The Athenæum," page 114, 1839. Talbot prepared the paper immediately on hearing of the discovery of Daguerre (see "The Week in History," January 20), but the work which he describes had been done some years before.

The Letters of Niépce.

Seventy-eight years ago Nicéphore Niépce was groping among the problems of photographically engraved plates and cautiously receiving the overtures of M. Daguerre as to a partnership. Writing to his friend Lemaitre on February 2, 1827, he asks: "Do you know one of the inventors of the Diorama, M. Daguerre? This gentleman has been informed—how, I cannot say—of the object of my researches. In January last year he wrote informing me that for some time past he had been at work on the same problem, and asking if I had been more fortunate than himself. It appears that he has already obtained some astonishing results, and yet I am surprised at his inconsequential request for me to tell him if I think it possible. I have been extremely reserved and discreet in my reply, though I wrote him frankly and courteously in order to encourage him to write again. His second letter arrived to-day, after a year's interval of silence, and now he only writes to know if I am still here. He asks me to send him a print, as he doubts whether it is possible to reproduce shadows entirely by this process of engraving, for which reason his own experiments have been made in another direction, whereby he aims at one perfect result instead of a number of copies. . . . Kindly say if you know Daguerre personally, and, if so, what your opinion is of him? . . . I send you five plates. The largest is the copy of an engraving of the Virgin, the Infant Jesus, and St. Joseph. The other four smaller ones are copies of a portrait and a landscape. These images, as you see, are not in varnish, but are very feebly engraved on the plates with acetic acid, no stronger than wood vinegar. The engraving is very slight in the case of the landscapes. I believe I have met with fair success in the case of the portrait."

Replying to Daguerre on this same February 2, Niépce wrote: "I have received your letter of January 25. I have done nothing for the past four months as the weather has been bad, yet I have improved my process of engraving on metal, although I cannot accede to your request, as the method has not yet given me sufficiently correct copies. I regret this course more for myself than for you, since your process is quite different, and offers a degree of superiority to which engraving cannot approach. This, however, does not prevent me from wishing you every success."

HISTORICS.

PROFESSOR ERNST ABBE.

The Story of Zeiss Lenses and Practical Philanthropy.

IN reviewing the work of Professor Ernst Abbe, whose death it was our painful duty to record last week, we are conscious of the difficulty of refraining from superlatives in speaking of a man who was first a great scientific investigator and afterwards became even more distinguished for his practical philanthropy. Professor Abbe was born at Eisenach, on January 23, 1840, so that had he lived a few days longer he would have celebrated his sixty-fifth birthday. His student days were spent at Jena and Göttingen, and he afterwards established himself in the former town as tutor in mathematics, physics, and astronomy. In 1866 he entered into those relations with Carl Zeiss which were to determine the whole course of his career. Twenty years previously Zeiss had founded a small optical workshop in Jena. Microscopes were among his manufactures, and, like other opticians of his day, he designed them by a tentative method of trial and error. But he was convinced that he could base his designs on scientific principles and could work by calculation alone instead of by the laborious processes which were then adopted. He found himself unequal to the theoretical part of that task, but in 1866 he associated himself with Professor Abbe, who, in consequence thereof, turned his scientific work in the direction of the microscope. Of Abbe's researches in microscopy it is out of our province to speak at length, revolutionary though it were. Its present interest for us was the fact that it was the beginning of great developments in all branches of optical industry.

It was not long before Professor Abbe found that for certain lens combinations he required entirely new descriptions of glass. "For years," he wrote, "we carried on, in addition to our actual work, investigations of combinations of imaginary and non-existent glasses and discussed the progress which might become possible if the producer of the raw glasses could only be made to take an interest in higher optical problems." A report on the state of microscopic optics drawn up by Professor Abbe on the occasion of the exhibition of 1876 of a loan collection of scientific instruments in London fell into the hands of Dr. Otto Schott, of Witten, in Westphalia. Dr. Schott was a chemist and established in the glass industry. The force of Professor Abbe's appeal to the glass makers led to his associating himself with the work, and in 1881 he commenced at Witten the preparation of glasses which Professor Abbe and his assistant, Dr. Riedel, at Jena, proceeded to subject to optical examination. This

first series of tests were on a small experimental scale, and were made to determine the relationship between the chemical composition of a glass and its optical properties. In two years very promising results had been obtained, and the experimental work was then continued on a large scale with the aid of monetary grants from the Prussian Minister of Education. These further researches led, in the autumn of 1884, to the establishment of a glass factory, and the "Glastechnisches Laboratorium Schott und Genossen" is now as famous as the Carl Zeiss Optical Works, the progress of which it has advanced as it has that of optical factories of all descriptions. The Jena glasses have opened new fields, not in photographic lenses only, but in telescopes, microscopes, and other optical instruments. The story of anastigmat lenses which we had occasion to tell when recently interviewing Dr. Rudolph's work is one only of the immense developments which have followed in the train of Professor Abbe's researches.

Apart from his scientific work, Professor Abbe led an uneventful life. He lived within a stone's throw of the Carl Zeiss factory, in a small, old-fashioned house, and his habits were the simplest. Soon after the death of Carl Zeiss he became the sole proprietor of the optical factory, until 1891, when he took a step which gave to the works a character unlike that of any other industrial undertaking. He resigned all his proprietary rights in the optical works and the glass factory. By this act he created the Carl Zeiss "Stiftung," or trust—the translation is not the happiest one, but it is the best English equivalent—and in 1896 its laws were confirmed by the Kultus Department of the Grand Duchy of Saxe-Weimar, and profit sharing was introduced to commemorate the fiftieth anniversary of the founding of the business. The constitution of the "Stiftung,"

the crown of Professor Abbe's life, provides a complete system of pensions, sick benefits, and profit sharing for all those employed under it. No profits accrue to individuals. The "Stiftung" devotes the surplus which remains after the payment of the above charges to the endowment of Jena University, and the sums which have been granted for this purpose amount, we believe, to more than £100,000. Professor Abbe's salary as director of the optical works could not be more than ten times the wages of a standard workman, and on his retirement in 1903 he drew the pension provided by the "Stiftung." Thus it is that the world is poorer by the loss of a man who laid the foundations of a great industry, who saw his work multiplied in a hundred ways, and who passed the last years of his life in securing to those who had shared in his labour the rewards of long and patient work.

THE LATE PROFESSOR E. ABBE.
(Photo. Bräunlich and Tesch, Jena.)

THE Edinburgh Photographic Society has an Art Union in connection with its annual exhibition. Prizes to the extent of at least £11 will be purchased from amongst the pictures exhibited, and that irrespective of the Judge's awards. The winners of prizes shall be entitled to select the pictures they wish; but they must do so and intimate their choice to the Hon. Secretary on or before the closing of the exhibition, after which date the right of choice shall vest in the Council.

WORKMAN'S Compensation.—A Tunbridge Wells man named George Marshall, who for some years had been in the employ of the Photochrome Company, Limited, and did artistic work in connection with picture postcards, met with an accident on June 21 last. A piece of wood fell on his right hand, fracturing one of his fingers. In an action brought by him against his late employers for compensation at the Tunbridge Wells County Court, he obtained a verdict for the payment by the defendant firm of 4s. a week until further notice.

ON THE COMPOSITION OF THE SILVER IMAGE TONED WITH VARIOUS METALS.

It is well known that prints obtained by development may be toned with various metallic salts. The only practical processes are the toning processes with uranium, iron, and copper. Up to the present the composition of the images toned with the said salts has not been determined, and believing that this question has a certain interest, we have analysed the images toned with the salts of uranium, copper, and iron, and also compared the results with the most probable hypothesis of their action.

Of the numerous formulæ for the said toning baths, we have chosen the commercial preparations known as "chromogènes Lumière," which are mixtures of powders, which can be kept without alteration, and which contain the various reagents necessary for toning in the best possible conditions.

The Method of Analysis.

In our experiments twelve ordinary 13 by 18 cm. negatives obtained by development on Lumière's "Blue Label" plates were toned. The negatives were carefully washed to remove every trace of hypo and then submitted for half an hour to the toning bath, in order to obtain as complete a conversion as possible of the silver. After toning, the plates were washed till the whole of the excess of the reagents was removed—that is to say, till the transparent parts were quite free from colour. The film was then removed from the glass, again washed, till all the soluble salts were removed, and finally dried and incinerated. The ashes were lixiviated with water and the potassium estimated as potassium chloroplatinate. The residue was dissolved in boiling nitric acid and the elements estimated after they were separated. The residue, silver chloride, insoluble in nitric acid, was also analysed. Finally, the accuracy of this method was confirmed by the estimation of the pure ferrocyanides.

Certain dubious results were controlled by fresh analysis of the plate images, toned as described above, and also of metallic silver, which was obtained in a very finely divided state by reduction with formaldehyde, and left in contact with the toning baths for several days, and then thoroughly washed to remove the last traces of the toning bath.*

The Composition of the Chromogènes.

The various mixtures which we have called chromogènes contain one common constituent, ferriocyanide of potassium, which is designed to act upon the silver, and to convert it into ferrocyanide; they further contain a metallic salt, which acts on the ferrocyanide, and on which the colours of the toned images depends. This salt is ferric citrate for iron toning, uranium nitrate for uranium, and cupric chloride for copper toning. The two latter toning salts are mixed with an organic acid, the purpose of which is to dissolve the silver ferriocyanide which is formed by the action of an excess of ferriocyanide of potassium on the soluble silver salt which forms in toning. If the precipitate of silver ferriocyanide was not dissolved, the whites would suffer.

The copper toning is mixed with potassium citrate in order to dissolve the cupric ferriocyanide, which is insoluble in water, and which is formed by the mixture of the copper salt with the potassium ferriocyanide. The necessity of using potassium citrate prevents the addition of an organic acid, for the cupric ferriocyanide would not then dissolve in the potassium citrate. For this reason a copper salt, the chloride, is used, as its acid cannot form any soluble silver salt, and consequently no insoluble silver ferriocyanide can be formed.

* The analyses of precipitated silver, which was treated with potassium ferriocyanide as well as with the Chromogènes, proved the interesting fact that only in the former case was there complete reaction; in all other cases it was very incomplete, and there were considerable quantities of unconverted silver.

Analysis of the Toned Images.

Before the analysis of the toned images was undertaken, we estimated the composition of the images which had only been treated with potassium ferriocyanide, in order to determine whether in this operation, which may be considered as the first phase of the three methods of toning, pure silver ferrocyanide or a double ferrocyanide of silver and potassium was formed.

The following results were obtained:—

Percentage of the Metals found in the Mixture.		Reckoned as the Formulæ Below.	
No. 1.	No. 2.	$K_2 + Ag = (CN)_6 = Fe$	$Ag_2 = (CN)_6 = Fe$
Silver ...	79.83 77.35	38.43	88.52
Iron	19.22 20.99	19.93	11.47
Potassium	1.38 1.65	41.63	—

These numbers appear to show that the silver is substituted for almost the whole of the potassium, and that the image is not formed by an estimated definite compound, but is more likely the result of an incomplete reaction.

The product of the reaction of potassium ferriocyanide on very finely divided silver was also analysed, and this had been left for two days in contact with the ferriocyanide. The following results were obtained:—

Silver	88.66 per cent.
Iron	10.57 per cent.
Potassium	0.16 per cent.

These numbers are very near those which may be reckoned for pure silver ferrocyanide. The reaction is in this case also more complete than in the presence of gelatine, which serves as the vehicle. One may thus assume that silver ferrocyanide is formed.

Below are the results of the analysis of the images toned according to the three methods, and the numbers are reckoned for 100 parts of the mixture of the metals. In copper toning, besides the metals in the state of ferrocyanide, a considerable residue was found, which was insoluble in nitric acid, and which consisted of silver chloride:—

	Iron Toning.	Uranium Toning.	Copper Toning.
Iron	67.35	21.89	30.99
Silver ...	31.89	30.0	36.56†
Potassium	0.76	1.22	4.39
Uranium	—	46.89	—
Copper	—	—	28.04
	100.0	100.0	100.0

Conclusions.

When the numbers thus found are compared with those which correspond to the formulæ of the substances, which can be formed in a normal way by the action of the silver ferrocyanide, which is formed in the first phase of the toning, on the different metallic salts, which are the actual toning agents, there is no agreement. In all cases the numbers found appear to stand between those which correspond to two formulæ; the one, in which the silver is partly substituted

† In the image toned with copper, silver chloride was also found, which remained insoluble on treating with nitric acid. The weight of the silver contained in the silver chloride is somewhat greater than that which was found in the silver ferrocyanide (120:100). No notice is taken of this in the percentage calculation of the above given composition of the image.

by the metal which causes the toning, and the other in which this substitution is complete.

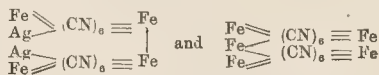

The small quantity of potassium found in the three kinds of images, which is far smaller than would correspond to a formula that would give the smallest quantity of this metal, can be considered from an incomplete conversion.

The images toned with uranium thus contain uranium, iron, silver, and a small quantity of potassium. Their composition appears to correspond to a formula, which lies between the two following:—

The elements which were found in the images toned with iron are iron, silver, and a small quantity of potassium. Their composition

appears to correspond to a formula, which lies between the two following:—

Finally, in the images toned with copper were found copper, iron, silver, and a small quantity of potassium, and a considerable quantity of free silver chloride.

The result of the analysis permits one to assume, disregarding the free silver chloride that its formula corresponds to one which lies between the two following:—

A. AND L. LUMIERE AND A. SEYEWETZ.

THE PROGRESS OF ORTHOCHROMATIC PHOTOGRAPHY.

DR. KOENIG, whose name will be readily recognised as the discoverer of the isocyanine dyes, which are now so much to the fore, contributes a useful article to the "Deutscher Camera-Almanach," of which the following is an abstract.

Every photographer and amateur, who knows anything at all of photography, understands what is meant by orthochromatic photography and orthochromatic plates, but it is not every one that rightly understands the subject, for some use orthochromatic plates and a yellow screen, whilst others see no advantage in the same. The real truth lies probably between the two, and it is only actual experience that enables one to appreciate the practical results of this scientific advance.

It is well known that, notwithstanding the correctness of the drawing and perspective given by photography, it has two great faults, the one the exaggerated difference between light and shade, and the other that it does not render colours in the same gradation or brightness as seen by the human eye. This false rendering of colour is particularly noticeable with yellows, or bright reds and blues; to our eyes yellows and red appear bright, and blues dark; by photography blue is rendered very light and yellow and red quite dark, because the gelatino-bromide plate is only sensitive to blue and violet and not for red, yellow, and green.

The Discovery of Orthochromatism.

In 1873 H. W. Vogel discovered that many dyes possessed the property of making silver bromide sensitive to red, yellow, and green, or, as it is usually called, "sensitised" for these rays. The first observation was made with collodio-bromide of silver, but other experimenters soon proved that gelatino-bromide of silver behaved in the same way, and now a very large number of dyes are known which sensitise gelatino-bromide of silver for the different regions of the spectrum. All these dyes also stain silver bromide direct, in the absence of gelatine, but it is a remarkable fact that not all dyes which stain silver bromide also sensitise. Whilst it has not yet been satisfactorily explained why only certain dyes possess sensitising properties, yet there is a certain connection between the absorption spectrum of the dye and the band of sensitiveness. The maximum of the sensitising lies at about the same place as the maximum absorption band of the dye solution; thus generally sensitisers for green and greenish yellow are red, and sensitisers for yellow and red are violet or blue.

The most important sensitisers for green and yellow belong to the phthalains, the best sensitisers for red are the cyanines. To the

first class belong eosine (tetrabromofluoresceine), diiodofluoresceine, and erythrosine (tetraiodofluoresceine). The maximum of sensitising lies with eosine in the green, and does not reach the Fraunhofer line D; with erythrosine the sensitiveness extends to beyond D; diiodofluoresceine lies between the two. Erythrosine must be considered as the strongest and best sensitiser for practical work.

The various dyes may be used in one of two ways: they may be either added to the emulsion before coating or ordinary dry plates may be bathed in very dilute solutions of the dye. The amount of dye to be used must be very minute, too much dye lowers considerably the general sensitiveness of the plate, as the deeply-dyed film prevents the penetration of the light. With all dyes the best results are obtained by bathing the plates.

The Yellow Screen.

If a colour chart is photographed with an erythrosine-bathed plate-chrome yellow will appear almost as bright as ultramarine; red, on the other hand, appears absolutely black. If it is desired to drive the orthochromatic action further, and to render yellow considerably brighter than blue, a yellow colour filter must be used, which damps the blue. The action of the colour screen does not seem to be thoroughly understood. If we realise that the so-called orthochromatic plates are always pre-eminently sensitive to blue, and that while on account of the proportion of blue rays in it must always exert the strongest photographic action, we shall easily understand that by the insertion of a yellow screen, which partially absorbs the blue rays, the exposure must be prolonged in order to obtain the same density in the whites. If two exposures are made on orthochromatic plates, one without a filter, the other with a bright yellow filter, and exposes the second twice as long, so that white has equal density in both, the blues will appear much weaker on the second plate than on the first; yellow, on the other hand, will appear much the stronger on the second than the first. By the increased exposure the yellow rays, which are not absorbed by the yellow screen, have acted more strongly on the yellow sensitive film.

It is obvious, therefore, without further explanation that a plate which is only slightly sensitive for yellow requires a darker yellow screen (and therefore a longer exposure) for correct colour rendering than a plate which is strongly sensitive to yellow.

Commercially as a rule, plates sensitive to greenish yellow, and which are usually sensitised with erythrosine, are called "orthochromatic," although they are not sensitive to red. Most of these plates only give a satisfactory orthochromatic action with a dark

yellow screen. The idea has been adopted for some plates of placing the yellow screen in the sensitive film, and the plates thus prepared permit of good colour rendering without a yellow screen.

The Cyanines.

We have mentioned above the second group of sensitisers—the cyanines. To this class belongs cyanine, a beautiful blue dye, which is an excellent sensitiser for yellow, orange, and red. Unfortunately this dye does not give reliable results, as the plates sensitised with it do not keep, and are prone to spots and fog. More important and more valuable from a practical point of view are the violet isocyanines, which are derived from chinaldin, because they not only possess the property of sensitising silver bromide for red, orange, and yellow, but make it also sensitive to green. The isocyanines combine therefore to some extent the properties of erythrosine with those of cyanine. With ethyl red, which was introduced by Professor Miethe, the nearly complete band of sensitiveness extends from the blue to the orange to just beyond the D line, the band of orthochrome T extends further into the red, and that of pinachrome extends even, with a short exposure, to beyond the C line in the red. Practically this means that plates sensitised with pinachrome are much more sensitive to orange and red than orthochrome plates, and more so still than ethyl red plates. Pinachrome must be considered as the best sensitiser known up to the present.

With these dyes the bathed plates are considerably more sensitive to colour than those coated with dyed emulsion.

With the aid of the said isocyanines or of mixture of dyes which supplement their sensitising properties, plates can be prepared which are sensitive to all the colours of the spectrum, even if not to quite the same degree. These "panchromatic" plates have also their maximum sensitiveness in the blue. The principal use of such plates is for colour photography, but their use is absolutely indispensable when orange and red have to be reproduced; for such work the interposition of an orange filter, to damp the blue and green, is always essential. It may be mentioned that up to the present no plate exists which is even approximately as sensitive for red as for blue.

The Use of Orthochromatic Plates.

Very different opinions as to the use of orthochromatic plates are held generally. Undoubtedly ortho-plates in conjunction with a colour filter are useful in innumerable cases, and frequently absolutely essential. It does not appear, however, correct to the author to recommend the universal use of ortho-plates for all landscape, and especially for mountain work, for it makes the photographer think that it is actually impossible to take ordinary landscapes with an ordinary plate. When yellow and yellowish green tones predominate, as in autumn or spring, or evening scenes, the ortho-plate can always be used with advantage, and in portraiture their use saves much retouching. Ortho-plates are absolutely essential in the reproduction of all coloured objects. The frequently described great advantages of the orthochromatic process in the taking of summer-green landscapes, of mountain peaks and distance, the author denies, although he is convinced that this heretical opinion will be frequently disputed.

As regards landscapes in summer, we ought not to forget that every kind of plate is very little sensitive to the dark green of summer leaves, and further that in a bright light, and much more in sunshine, it is the white light reflected from the leaves much more than the green that produces the photographic image. As a matter of fact, the author has never succeeded in confirming a difference between orthochromatic and ordinary plates for ordinary landscape work.

It is just the same with mountainous and distant scenery; with these the yellow screen and ortho-plates should work wonders. The author certainly believes that many amateurs obtain better results with the aid of these two, but the pictures are only better because

the true exposure is mostly involuntarily rendered shorter by the yellow screen, or, what comes to the same thing, the ortho-plates are frequently less sensitive than the ordinary. If the ordinary plate is only exposed for a sufficiently short time the cloudless blue sky will also appear darker in the print than the snow peaks glistening in the sun; and if the sky during the exposure is whitish, so that the mountain is visually almost impossible to detect, then no orthochromatic plate and no yellow screen is of any avail to obtain a difference.

It may be argued that the use of orthochromatic plates can at least do no harm. Opposed to this are the facts that ortho-plates are mostly dearer than ordinary, and frequently are inferior as regards keeping properties and sensitiveness, though, as we have already seen, this last may be an advantage under certain conditions. Finally, the exposure is considerably lengthened by the yellow screen which must generally be used.

The photographer will do well to consider in every case whether the use of ortho-plates appears advantageous or not. As a guide to this point a few short rules may be useful, which embody what we have said.

When to Use Ortho-Plates.

1. According to the prevailing method of speaking we differentiate between orthochromatic and panchromatic plates. The former are only sensitive for yellow and yellow-green; the latter are also sensitive to orange and red.

2. The commercial orthochromatic plates only permit of an absolutely correct colour rendering, as regards yellow and blue, when used with a yellow screen of more or less dark shade.

3. The use of orthochromatic plates is above all things necessary when the reproduction of yellow and yellow-green is in question. For bluish green and dark green the plates, even with a yellow screen, are very slightly sensitive, so that for ordinary landscape work, further for mountain and distant scenery, the ortho-plates offer no important advantages.

4. Panchromatic plates are certainly necessary when orange and red are to be reproduced, and in this case the use of colour filters is absolutely essential.

5. Bathed plates are always more sensitive than plates dyed in the emulsion.

Formulæ for Bathing.

Always use perfectly clean working plates, and bathe them in the dark, keeping the solution continuously on the rock. After bathing, the plates should be washed in running or frequently changed water for two or three minutes, and dried in a well-ventilated place free from dust.

Erythrosine Bath.

Water	100 ccm.
Ammonia	2 ccm.
Erythrosine solution (1:1,000)	6-8 ccm.

Bathe for 2-3 minutes.

Pinachrome Bath.

Water	100 ccm.
Ammonia	1 ccm.
Pinachrome solution (1:1,000 alcohol)	2 ccm.

Bathe for 3-4 minutes.

Ethyl red and orthochrome plates are prepared in exactly the same way as the pinachrome plates.

At Brentford, on Friday last, Herbert Meek, a photographer, of Staines Road, Hounslow, was remanded on his own bail, charged with embezzling £2 9s. 7d., and further, with obtaining by false pretences a camera and stand of the value of £21, the property of Mr. Francis Crichton Temple, a son of the late Sir Richard Temple, M.P. for the Kingston division of Surrey, and managing director of the Phototype Company, Hounslow.

Photo-Mechanical Notes.

A Convenient Reducer.

THE reduction, or "cutting," or "clearing" of wet plate negatives is usually done by first bleaching the negative in a solution of iodine in potassium iodide, afterwards flowing over with weak cyanide of potassium solution, and when reduction is complete, blackening the negative with ammonium sulphide, or sodium sulphide. This has the merit of enabling the operator to work on a white bleached image; on the other hand, since iodine (and iodide of potassium) costs upwards of ten shillings a pound, it is an expensive method. Sometimes the iodine solution is added to the cyanide solution and that flowed over the plate. This "cuts" without bleaching, and so saves the necessity to subsequently blacken; but the reducer is just as expensive, in fact more so, for the bleaching method may be performed with the iodine in a dish, used over and over again, whereas with the iodine added to the cyanide it goes straight down the sink. There is, however, no necessity to use iodine at all, as instead of adding iodine to the cyanide, a few drops of 10 per cent. solution of ferricyanide of potassium will do just as well, and the cost of this chemical is only about 1s. 6d. per lb. This reducer also does equally well for dry plates as the common "Farmer's reducer" of hypo and ferricyanide; in fact, it seems to keep much better. The cyanide of potassium solution should be very weak; even 1 per cent. of good 30 per cent. cyanide cake will be found fairly energetic. Usually, wet plate operators in process houses do not work to definite proportions, but if one takes, say, 4 oz. of 1 per cent. cyanide of potassium solution, then $\frac{1}{2}$ oz. of 10 per cent. ferricyanide of solution will be found to work well.

Another method of reducing wet plates is to take some of the copper bromide intensifying solution, dilute to half strength with water, flow over the negative, wash, and afterwards flow with weak cyanide solution. This requires careful manipulation, but it will be found that even a lead-intensified negative can be reduced by this means.

Focussing in Three-colour Work.

It is necessary to focus for three-colour with the filter in position, and where liquid filters are used it is usual to replace the coloured fluid by plain water for convenience. Sometimes, however, it is impossible to get a sharp image under these conditions, and this will be found generally to be due to the fact that the cold water causes the moisture from the atmosphere to condense upon the sides of the glass cell, scattering the light coming from the subject, just as a piece of ground glass would do. It may happen, too, that water is spilled over the sides of the tank, and the collection of little globules distorts the image. The very simple remedy in both cases is merely to carefully clean the tank; focussing can generally be finished before a second condensation of moisture occurs.

Colotype without a Presse.

In the current number of the "Photographisches Wochenblatt," Herr Franz Hofbauer describes a simple process of colotype with gelatine dry plates which seems suitable for amateurs. By yellow light an ordinary dry plate is immersed in a 3 per cent. solution of potassium bichromate or a 4 per cent. solution of ammonium bichromate; it is then dried in the dark and exposed under a reversed negative, well washed in ordinary water, fixed in a 20 per cent. solution of hypo, and again washed and dried. The dry plate is now laid in a mixture of equal parts of glycerine and water to which 5 per cent. of alcohol has been added and allowed to thoroughly soak, and again superficially dried. It should now be laid on a soft bed—the author recommends a book of about 1,000 pages, opened in the

middle—and the plate is inked up with colotype ink, and a sheet of damp paper placed on it, and the book shut and placed in a copying press. The book is then removed and the paper carefully pulled from the plate. It is stated that from fifty to seventy prints can thus be made, and perhaps more after some experience. This recalls Balaguy's old process.

Enamel Formula.

In answer to a query received this week as to the best formula for the enamel process on copper and zinc, we may state that formulae for this are almost as numerous as the sands on the sea shore, and the best happens to be just the one which suits the operator. The following, however, we know to be in use by a good operator:—

Le Page's liquid glue	8 oz.
Egg albumen	2 oz.

Mix thoroughly, and then add the sensitiser, which is composed of

Ammonium bichromate	1 oz.
Water	16 oz.

To the above quantity of albumen and glue add

Bichromate solution	5 oz.
Water	16 oz.
Ammonium citrate	50 grs.

This may be used for both copper and zinc.

Transferring Newspaper Drawings.

A method of transferring printed drawings for photographing is of occasional service to the photo-engraver, and though the following process is not new, it may be worth while to quote it from the "Inland Printer":—"Dissolve $\frac{1}{2}$ oz. of common yellow soap in 10 oz. of hot water. Cut the soap into shavings to dissolve more easily. When it is cold, add 2 oz. spirit of turpentine and mix thoroughly. Pour this solution into a shallow dish and float the picture you wish to transfer on it, face down, on the solution. When the paper has taken up all it will, lay it, face down, upon a blotter to absorb all the surplus moisture. Now, to transfer, lay the damp print face down on a piece of Bristol board with a piece of thin tracing or Manila paper over it; fasten one side of the print with its cover paper securely; then rub the cover paper hard with a burnisher in lines away from the side fastened. The ink will leave the print and go over to the Bristol board wherever the burnisher has passed. The danger to be avoided is the shifting of the print during the burnishing operations, but this will be guarded against with practice."

The immense saving of time to printers by the use of carefully prepared overlay cannot be overestimated, and Mr. C. W. Harness, of Wolverhampton, is supplying to every one who orders a block from him an "Alrevo" overlay, which, it is stated by the "Inland Printer," is to be prepared as follows:—"A sheet of very thin and transparent celluloid is coated with bichromatised gelatine, exposed to light under a negative, and the soluble parts then washed away, the whole process being very similar to the carbon process. The inventor lays great stress on the value of the transparency, which, he claims, enables the pressman to see exactly where to place it upon his make-ready."

THE death of Mr. Silas Daniel, photographic chemist and dealer, of Swindon, Wilts, took place on January 15.

THE death by suicide is announced of Mr. William Fryer, of Terry and Fryer, photographers, Worcester. The deceased gentleman retired to rest on Wednesday night, January 18, apparently in the best of health, but was found in the morning suspended by a strap at the foot of the bed.

Exhibition.

GRANTHAM INDUSTRIAL AND ART EXHIBITION.

THE following were the awards in the photographic section (open to amateurs in the United Kingdom) of the above exhibition, the judges being Messrs. H. Preston and A. W. Anderson:—

Class 54.—Landscapes, Seascapes, and Interiors, half-plates and under, in sets not exceeding six: 1, Rev. E. T. Clark; 2, Mr. A. W. Walburn; 3, Mr. H. N. Rainbow.

Class 55.—Landscapes, Seascapes, and Interiors, over half-plate, in sets not exceeding six (open): 1, Mr. J. E. Latham; 2, Mr. P. T. Deakin; 3, Rev. E. T. Clark.

Class 56.—Portrait and Animal Studies, half-plates and under, in sets not exceeding six (open): 1, Mr. A. W. Nicholson; 2, Mr. J. Smith; 3, Mr. N. O. E. Meade-King.

Class 57.—Portrait and Animal Studies, over half-plates, in sets not exceeding six (open): Mr. J. Smith.

Class 58.—Enlargements (open): 1, Mr. R. N. de Pinto; 2, Mr. J. Wilmore.

Class 59.—Figure Studies, Plants and Flowers, or Lantern Transparencies, in sets not exceeding six: 1, Mr. L. C. Wilson and Mr. J. H. Miller; 2, Mr. H. N. Rainbow.

FORTHCOMING EXHIBITIONS.

January 14-28.—The Scottish National Salon. Hon. Secretary, W. A. Frame, 28, Bank Street, Hillhead, Glasgow.

January 20-21.—South Essex Camera Club. Hon. Secretary, T. Mitchell, 180, Browning Road, Manor Road, E.

January 23-28.—Lancaster Photographic Society. Hon. Secretary, R. T. Simpson, 21, Cheapside, Lancaster.

January 28-February 12.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grand-Armée, à Marseille.

January 31-February 4.—Cardiff Windsor Amateur Photographic Society. Hon. Secretary, Mr. G. Gallon, 37, Hamilton Street, Cardiff.

February 6-11.—Blairgowrie and District Photographic Association. Hon. Secretary, Wm. D. M. Falconer, James Street Cottage, Blairgowrie.

February 15-March 15.—International Exhibition Artistic Photographs, Vienna. Hon. Secretary, Dr. Reiniger, Camera Club, Largerplatz No. 3, Vienna III., 3.

February 16-18.—Norwich and District Photographic Society. Hon. Secretary, E. Peake, Rydal House, Earlham Road, Norwich.

February 21-March 7.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

February 24-March 4.—Northampton Photographic Society. Entries close February 7; for pictures, February 17. Hon. Secretary, E. J. Felce, 85, Adam's Avenue, Northampton.

February 25-March 4.—Birmingham Photographic Society. Hon. Secretary, Lewis Lloyd, Norwich Union Chambers, Congress Street, Birmingham.

February 25-March 11.—Edinburgh Photographic Society. Entries close February 11; for pictures, February 15. Hon. Secretary, J. S. McCulloch, 3A, North Saint David Street, Edinburgh.

March 4-11.—South London Photographic Society. Hon. Secretary, H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 7-14.—Brentford Photographic Society. Hon. Secretary, F. H. Read, Ferndale, Clifden Road, Brentford.

March 20-25.—The Cripplegate Photographic Society. Hon. Secretary, John B. Parnham.

March 27-April 1.—Leicester and Leicestershire Photographic Society. Entries close on March 20, 1905. Secretary, R. Warden Harvey, Oriental Cafe, Market Place, Leicester.

April.—International Exhibition, Genoa. Sec. Gen., Piazza Fontane Marose 18, Genoa.

April 3-15.—Photographic Society of Ireland. Hon. Secretary, R. Benson, 35, Molesworth Street, Dublin.

April 7-May 8.—International Artistic Exhibition, Berlin. Director, Herr Franz Goerke, Maassenstrasse 32, Berlin, W.

May 1-31.—International Exhibition of Photographic Picture Postcards, concurrently with the 10th Salon. M. le Secrétaire Général du Photo Club de Paris, 44, Rue des Mathurins, Paris.

June.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

March 31.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Limited, Ilford, E.

September.—Kodak. £400 in prizes for results on Kodak products. Kodak, Ltd., 57-61, Clerkenwell Road, London, E.C.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents were made between January 9 and 14, 1905:—

SHUTTERS.—No. 433. "An improved time valve for photographic shutters." H. A. Crabb, 23, Southampton Buildings, Chancery Lane, London.

COLOUR EFFECTS.—No. 559. "Improvements in the production of colour effects on photographic paper." A. C. Ponton and W. C. Horne, Rylestone, Bromley Road, Catford, London.

TRIPDS.—No. 561. "Improvements in tripods and stands, and means of attachment between tripods and stands and cameras, telescopes, surveying and other instruments." H. Major, 24, Canholme Road, Forest Hill, London.

PRINTING FRAME.—No. 606. "An improved photographic printing frame." J. G. Pratt, 100, Wellington Street, Glasgow.

FLASHLIGHT.—No. 628. "Improvements in flashlight apparatus." F. F. Payne, 27, Chancery Lane, London.

PROTECTING PHOTOGRAPHS.—No. 639. "Means for beautifying and protecting the surfaces of photographs." F. E. Blaisdall, 22, Southampton Buildings, Chancery Lane, London.

SINGLE-PICTURE STEREOSCOPY.—No. 706. "An improved stereoscopic lens for viewing single pictures stereoscopically." W. Brierley, 52, Claylands Road, South Lambeth, London.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

FOCAL-PLANE SHUTTER.—No. 28,319, 1904. "The patentee claims protection for certain special mechanisms (which cannot be

described here in the absence of the drawings) for obtaining and showing the tension of the driving spring in revolutions, the width of the aperture between the blinds, and the speed at which the shutter is set, the tension width and speed being capable of being adjusted and set at will." C. E. Pollard, 120, Victoria Road, Woodstock, Cape Town.

FIRE PREVENTION IN CINEMATOGRAPHY.—No. 1,211, 1904. "Automatic mechanism to prevent a fractured film remaining in the rays of the projecting light, or being fed further towards it. By the closure of an electric circuit, on the film breaking, the light is extinguished or a shutter interposed between it and the film. The action is as follows:—By the action of two rotary sprocket wheels, working in conjunction with an intermittent motion between them, a loop of film is made, which is fed forward and then automatically taken up by various approved means, this action going on continuously. Two pieces of metal, electrically insulated from one another, are shaped to the loop of film above mentioned and fixed concentrically to one another and the loop of film, in such a way that, when the machine is working normally, the film clears the inner piece of metal, but immediately the film breaks, it (that is the loop of film) ceases to be taken up, and as the feeding sprocket wheel continues to feed the film forward, the loop immediately increases above its normal size and instantly presses against the inner piece of metal before mentioned, which is so constructed that the slightest pressure brings the latter in contact with the outer piece of metal, thus closing the electric circuit." C. C. Schiller and S. J. Roxblade, St. Albans Chambers, 17a, Long Row, Nottingham.

MULTIPLE TISSUE FOR COLOUR PHOTOGRAPHY.—No. 4,941, 1904. "The compound tissue is designed to produce single or double transfer prints in colours at one operation from ordinary negatives. The tissue consists of layers of pigmented gelatine arranged in the order, from back to front of the paper, of blue, yellow, green, red, and black; the most transparent being uppermost, and the more opaque underneath. This arrangement is recommended for landscape negatives, but in order to prevent the blending of the colour of adjacent films, other layers of contrasting colours are interposed, and the series of films may run as follows, from top to bottom:—Blue, greyish pink, yellow, red, green, and black, with a deep red non-actinic film below this to prevent the picture adhering to the paper. To form the printing surface, the paper or other support has applied to it the different gelatine solutions in succession, each layer being allowed to set and dry before the next is applied, so that the adjoining layers will not mix. In making a printing paper, for instance, the strip of paper is carried on rollers and is run successively through baths of different coloured gelatine solutions. The thicknesses of the layers may be adjusted by varying the speed of the paper, and the temperature of the bath. Thus with a quick speed of the rollers and a low temperature a thick coating will be obtained and vice versa. The colours employed are of the usual kind for colouring pigment or carbon papers." W. Adolf Heseckiel, 2, Lützowstrasse, Berlin.

SENSITIVE LEUCO DYES.—No. 4,994, 1904. "Protection is claimed for (1) the manufacture of sensitive surfaces for photography by applying the leuco body from an organic dye in admixture with a compound containing one or more loosely combined nitro groups. (2) The use of a carrier of oxygen to enhance sensitiveness. (3) Sensitive surfaces prepared according to (1) and (2). (4) A photographic process on these lines; the image being fixed in a solvent of the leuco-dye; and (5) and (6), the application of the process to three-colour photography. Suitable nitro bodies are the nitro acid esters of carbohydrates such as the so-called nitro-cellulose,

nitro-glucose; also nitrosamines, such as those of methyl-phenyl, and diphenyl. The solvents of the leuco bodies, which serve as fixing agents, are hydrocarbons of the benzene series, chloroform, carbon tetrachloride, and weak organic acids, particularly monochloroacetic acid. The carriers of oxygen mentioned by the patentees are platonic chloride, aniseed oil, turpentine oil, and quinoline and its homologues. By this process leucaniline yields a red image, hexamethyl-para-leucaniline, a blue-violet image, the leuco-bases of the malachite green series a green to blue image and the leuco bodies of flavaniline, uranine and the like, yellow images. The examples of the process given in the patent need not be quoted, as the process has already been described at length in THE BRITISH JOURNAL OF PHOTOGRAPHY, October 14, 1904, page 886, and October 21, 1904, page 908." O. Imray, Southampton Buildings, London, acting for Meister, Lucius, and Brünig, of Hoechst-on-Maine, Germany.

STABLE HYDROSULPHITES.—No. 7,397, 1904. "The method of obtaining the solid hydrosulphite—or hyposulphite, as it is termed by chemists—consists in heating the hydrosulphite with a liquid which is able to take up water. The hydrosulphite is afterwards dried in a vacuum over sulphuric acid." J. Y. Johnson, 47, Lincoln's Inn Fields, London, for the Radische Anilin und Soda Fabrik, Ludwigshafen-on-Rhine, Germany.

DAYLIGHT DEVELOPMENT AND FIXING.—No. 7,492, 1904. "The patented apparatus consists of a chamber of about the shape and size of a dark slide. On one side is a ruby window, on the other a window of plain glass. This latter is covered by a shutter, which is withdrawn after the operator has inserted his head in a hood which screens this side of the apparatus." O. Zwieback and Sydney Hall, 22a, Escherheimer Landstrasse, Frankfurt-on-Maine, Germany.

ROLLER SLIDES AND SHUTTERS.—No. 23,518, 1904. "Improvements on the mechanism of a shutter and roll-holder working in conjunction, as described by the present patentee in specification No. 4,392, 1902." F. Pascal, 7, Chemin Montbrillant Prolongé, Lyon-Monplaisir, France.

X-RAYS and Bankruptcy.—In the London Bankruptcy Court last week it was stated by an X-ray expert and skin specialist, that his business had been crippled by newspaper allusions to the injurious effects of X-ray treatment at the hands of certain operators.

A PHOTOGRAPHIC record of the great hoard of Roman coins discovered at Croydon in 1903 has been made by Mr. G. H. Baldock, F.C.S., who contributes a few notes on his work to the report on the coins by Mr. G. F. Hill, of the British Museum. Mr. Baldock, whom we congratulate on this valuable work in the interests of a branch of photographic survey, writes:—"I asked the Croydon Council to allow me to do it; this request they cordially granted, and placed the whole collection and also a spare room at my disposal. In this room I spent all my spare time for six weeks, and photographed some 250 coins on 50 plates. The object I had in view was to represent as many types as possible; in some cases there were a large number of coins of the same type; of these I selected the best; in other cases there was but one coin, and that in none too good a state of preservation, consequently two plates had to be used for these, one for the obverse and one for the reverse. From my series of photographs, a selection has been made for reproduction in this pamphlet in fifteen plates, of those which show most distinctly and of the rarest coins. Photographers will know that, perhaps, the best way of copying coins is first to make a plaster cast of them, and from that cast another in relief, but as that is obviously a long process, I simply used the coins themselves, rubbing them up a little to remove some of the verdigris and dirt adhering to them."

New Books.

"The Zeiss Works and the Carl Zeiss Stiftung in Jena." By Felix Auerbach. Translated by Siegfried F. Paul and Frederick J. Cheshire, F.R.M.S. Published by Marshall Brooks, and Chalkley, Ltd. Price 2s. 6d.

It is fitting that this history of the Carl Zeiss Works should reach our table when we are reviewing the life of him who was the founder of the now famous "Stiftung." In Herr Auerbach the Zeiss Works have a sympathetic historian and the translators have excellently done their work with an eye to the preservation of the spirit of the original, rather than to the literal transcript of the German edition. The whole history of how the two great allied factories at Jena—the glass works and the optical establishment of Carl Zeiss—sprang from the humblest beginnings reads like a page of romance. Herr Auerbach likens the progress of the Zeiss industry to that of Siemens and Halske. "In both cases," he says, "the gigantic development can be traced to the fact that a man who, until that time had no practical experience of the particular line of business became connected with the concern: in the first case, it was the artillery officer, Werner Siemens, who joined Halske; in the second, it was the university don, Ernst Abbe, who joined Carl Zeiss." Herr Auerbach traces and very fully illustrates the history of Zeiss from the time of his establishment in a small workshop in the Neugasse at Jena. His association with Abbe and the enterprises of the latter with Schott, which led to the new Jena glasses, are considered at length, until we come to the highly-organised optical works with its 1,500 workpeople, its twenty scientific collaborators, and its varied products in optical instruments. The later achievements of the Carl Zeiss works in the construction of microscopes, telescopes, photographic lenses, and other instruments are treated in detail, and the last third of the book is devoted to the foundation of the "Stiftung"—that conception of Professor Abbe's which has proved perhaps the most remarkable and successful experiment in social problems made within the memory of the present generation. Herr Auerbach's volume will be read with equal interest by photographers and political economists.

"Photography for the Sportsman Naturalist." By L. W. Brownell. Published by Macmillan and Co. Price 8s. 6d. net.

The author's title accurately describes this bulky volume of over 300 pages, which concerns itself with photographic ways and means to be pressed into the service of a hunter with the camera. Nevertheless, if we except the chapters on photographic processes pure and simple, there is scarcely a page which will not interest lovers of birds, beasts, and reptiles. The author has lived among the animal life of America for the purpose of depicting them and their customs as the Kearton Brothers and others have done in this country. Perhaps his work is not equal photographically to the Keartons', but he has hunted all kinds of game with his lens, from the elk to moths and dragon-flies. If he says less about natural history, he is more explicit on photographic methods than his compeers. The earlier chapters treat of the outfit of the sportsman-photographer, are commendably free from technical language, and full of the writer's practical experience. In the later portions the photography of the different classes of subject is dealt with—the larger and smaller animals, birds, and their young, insects, fishes, wild flowers, trees, and fungi. The volume contains a number of half-tone illustrations selected from the author's collection of 3,000 negatives, and if they are not printed as well as might be we must set this to the account of the paper, and be thankful that a dead surface makes for pleasant reading.

New Materials.

A dark-room lamp specially designed to take the seven Flexoid filters recently reviewed in this column is now being supplied by Messrs. A. E. Staley and Co., 19, Tavies Inn, London, E.C. The construction of the lamp is such that any or all of the filters can be at once put in position. Messrs. Staley will be pleased to show the apparatus to any one who will give them a call.

The Rotary Stripping Pigment Film. Sold by the Rotary Photographic Co., Ltd., 12, New Union Street, Moorfields, London, E.C.

This new film for the carbon process considerably simplifies a process which is already very simple and easy to work, but which to many presents some difficulty on account of the necessity of the double transfer. The pigmented gelatine of this film is coated on very thin celluloid, and printing is effected through this, thus doing away with the necessity for the safe edge, transfer before development, and the double transfer.

The film is sensitised in a 3 per cent. potassium bichromate bath, rendered alkaline with ammonia for normal work, though of course this may be adjusted to the negative as usual, the time of immersion being one minute. Drying is effected in the usual way, the film being temporarily fastened to cards. When dry, the back of the film must be carefully cleaned, and is then placed in contact with the negative, and the necessary insolation determined by a photometer. In the instructions issued by the makers attention is drawn to the fact that certain colours are more sensitive than others, and considerably more sensitive than P.O.P.

Development is effected by merely placing the exposed film in a dish of water between 85 and 105 deg. Fahr., no rocking or laving of the surface being necessary; in fact, this would be prejudicial, as likely to injure the delicate half-tones. When completely developed, which it will be in from five to ten minutes, the film is placed in cold water for a few minutes, and then allowed to dry. To mount the print on paper, the paper and film are soaked for a short time in lukewarm water, brought into contact, laid on a sheet of glass, air bubbles pressed out, and then squeegeed and placed under pressure, such as can be obtained between two pieces of glass in a printing frame for half an hour, and then removed and allowed to dry. When perfectly dry the celluloid can be stripped off without the slightest difficulty; the print is then lightly rubbed with benzine, and may be hardened by alum or formaline. If a matt surface is desired, the print can be squeegeed to ground glass and stripped whilst still moist. Rough paper may be used, but a little modification of the mounting process is essential, and greater pressure must be employed.

Lantern slides, stereo and window transparencies, can of course be made by the aid of these films, and a much wider range of colours is opened up for this work, as the stripping film is made in twelve colours.

This new introduction should certainly induce many to adopt the carbon process, and the ease and simplicity of working are very striking. We note also that special stripping films are made for three-colour printing.

J. MARTIN AND Co., the well-known trade printers and enlargers, of New Southgate, have sent us an attractive postcard which they have titled "The Frozen-out Spider," and which represents a spider's web covered with hoar frost. They also send us their latest price-list, which may be obtained on receipt of trade card.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Jan.	Name of Society.	Subject.
30.....	South London Photo. Society...	<i>Stereoscopic Work.</i> Mr. J. T. French.
30.....	Wakefield Photo. Society.....	<i>Ruined Abbeys of Yorkshire.</i> Rev. J. W. Beaulaud, M.A.
31.....	Luton Camera Club.....	Annual Exhibition Opens.
30.....	Camera Club.....	<i>The Magic Carpet.</i> Illustrated. Mr. Edw. Rimbaud Dibben.
30.....	Southampton Camera Club.....	<i>Our Chapter Houses.</i> Illustrated. Mr. E. W. Harvey Piper.

3.....	Watford Photographic Society	Members' Lantern Slides.
3.....	Boro' Poly. Photo. Society.....	Development. Mr. G. Wytne.

ROYAL PHOTOGRAPHIC SOCIETY

MEETING held January 24.—Major-General Waterhouse in the chair. Mr. William Taylor, of Leicester, read a paper on "Some Problems of Shutter Design" in which he emphasised the need of a commercial shutter which would work with reasonable closeness to the marked speeds, and which would also possess a high degree of efficiency. The focal-plane shutter, he admitted, had efficiency of 100 per cent. and there were several excellent shutters of this type on the market, but he was in agreement with Mr. Chapman Jones in objecting to this shutter when one "between the lens" could be used. In a shutter of the diaphragm type a double action took place as it opened; the rate at which the moving parts worked increased and at the same time there was acceleration of the light effect on the plate. In every shutter of this type it was necessary to distinguish between the durational and the effective exposure, and the lecturer was not certain to which of these photographers attached greater importance. To obtain great efficiency the shutter had to open fully, and close completely, as rapidly as possible, and to that end the mass of the moving parts and the distance through which they moved must be reduced to the smallest possible quantities. In constructing a shutter on the principle of the Iris diaphragm a reduction of weight was obtained by making the Iris of four leaves only, each weighing, in the specimen exhibited, only thirteen grains. In proof that a shutter of this light construction could be made strong enough to withstand continued work, the lecturer stated that he had submitted one to movements corresponding to 25 years' use at the rate of six gross of exposures per annum. Distinguishing between the two kinds of exposure, it was suggested that the terms "hand" and "automatic" should replace the time-honoured but inaccurate "time" and "instantaneous."

In considering the mechanics of a shutter the lecturer said that the control of the speed of automatic exposures by frictional methods had proved unsuccessful through a wide range of speeds, and he therefore fell back on the methods of pneumatic control, first employed, he believed, by Newman and by Adams. But it was greatly preferable to work the air in compression instead of in extension, and to reduce the capacity of the air reservoir according to the time interval to be controlled. The pneumatic accessory should perform the single duty of controlling the time, and should not be used also to arrest the moving parts. Mr. Taylor dwelt also on the advantage of springs in compression, not in extension, in shutter construction, and after describing the arrangement of springs to give a fixed motion to a certain part, showed how a variable motion could be obtained from it by a simple system of links. A specimen of a shutter, constructed on the above principle but not yet ready for the market, was shown, and was stated to open fully in 1-200th second, and to give exposures of 1-100th, 1-50th, 1-25th, 1-12th, $\frac{1}{8}$, and 1 second. The construction of the shutter permitted of automatic exposures being accurately given, and the position of the adjusting cam having been fixed for the two extreme speeds, the intermediate ones were obtainable by calibration.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE annual meeting of the members of this association was held on January 19, in the rooms of the Artists' Club, Eberle Street, Mr. F. A. Schierwater presiding. The reports of the secretary and treasurer, which showed the society to be in a satisfactory condition, were adopted. An important alteration of the rules defining the amateur status was moved by Dr. Thurstan Holland, seconded by Dr. J. W. Ellis, and adopted. Another alteration in the rules, providing that members under the age of twenty-one pay no entrance fee, was carried with few dissentients. The following were appointed officers for the ensuing year:—Dr. Thurstan Holland, president; Messrs. J. Marples and J. Appleby, vice-presidents; Mr. A. C. Batty, hon. secretary; Mr. W. Lockier (in place of Mr. P. H. Phillips, resigned), hon. treasurer; and Mr. W. A. Taylor, librarian. Nine vacancies occurred on the Council owing to resignations and retirements through rotation, and the following were elected:—Dr. Ellis, Rev. W. Smith, Lieutenant-Colonel Pilkington, and Messrs. Stuart, Newton, Schierwater, Petrie, Gregory, Jones, and Phillips. The President, on behalf of the association, presented to Mr. E. Simmet a beautiful Chippendale cabinet on his retirement from the secretaryship. The results of the annual competition were declared by the President as follows:—Class A, gold medal and trophy, Mr. C. F. Stuart; special medal, Mr. J. D. Johnston; class B, Mr. J. D. Johnston and Dr. Holland; class C, Lieut.-Colonel Pilkington and Mr. W. A. Taylor; class D, Mr. H. R. Heap; class E, Mr. F. A. Pendlebury and Mr. H. H. James; President's plaque, Mr. J. Smith; excursion prize (Lange plaque), Mr. Canevali; Mr. Taylor's prize, Dr. Ellis; and scientific class, Dr. Holland. Among the lantern slides, class F (gold medal) was won by Mr. H. Holt, class G by Mr. Richardson and Mr. W. A. Taylor, and class H by Lieut.-Colonel Pilkington and Mr. Prince. The bi-monthly competition was won by Mr. H. E. Cubley and Lieut.-Colonel Pilkington, and Mr. H. R. Heap's lecture prize by Mr. Taylor.

DERBY PHOTOGRAPHIC SOCIETY.

ON January 23 Mr. J. Page Croft demonstrated before a large number of the members of the Derby Photographic Society the possibilities of the gum-bichromate process. Mr. Croft, who was assisted by Mr. Howell, of Leicester, coated, sensitised, and developed a number of prints. The lecturer recommended that the paper be first coated with gum solution (1 oz. to 3 oz. water), and sensitised afterwards, in preference to it being performed in one operation, as is sometimes

recommended, and the following is the amount of colour he used to the drachm of 10 per cent. bichromate solution:—For a dead black, lamp black, 1 grain; for a warm black, vegetable black, $1\frac{1}{2}$ grains; for browns, brown colour, 2 to 3 grains; for reds, red colour, 4 to 5 grains. The ground colour was incorporated with the bichromate solution in a pestle and mortar, laid on with a hog-hair brush, and afterwards smoothed down with a badger softener. After the prints had been soaking in a cold bath for about five minutes to discharge some of the bichromate, Mr. Croft proceeded to develop with warm water, and said that if the prints had been under-exposed a piece of caustic soda (about the size of a pea to the pint of water) would quicken matters. He demonstrated the amount of control which would be obtained by the use of a brush in local development, but said that if the print, after being roughly developed, were dried and then re-soaked, at some future time of course, not being exposed to the light in the meantime, the surface became much tougher, and there was less risk of spoiling the print. He also said that it was not advisable to take the print out of the water too frequently during development, as if this were done there was a danger of washing some of the half-tones away.

Mr. Croft said that any good paper could be used as a base, but recommended Hollingsworth's Turkey Mill or Whatman Hot Press. If the paper used was very rough, or of a porous character, a preliminary sizing was an advantage, but this was not necessary with either of the two kinds mentioned.

The lecturer claimed that by modifying the coating, exposure, and development the process would give a much more varied range of texture, colour, and gradation than is possible with any other printing process, and the large quantity of gum prints made by himself, Messrs. Hill, Mummery, Gale, and Miss Warburg, which were passed round, fully justified his contention. The lecture was much appreciated, and the vote of thanks accorded to Messrs. Croft and Howell was very hearty.

BOWES PARK AND DISTRICT PHOTOGRAPHIC SOCIETY.

At the annual general meeting of this society on January 16 the retiring president (Mr. W. T. P. Cunningham), in presenting the report of the Council for the past year, stated that great improvement had been shown in the photographic work of the members during that time. The membership remains about the same, but is more active. With regard to finances, it was stated that there was a balance in hand on the year's work. The resignation by Mr. Kernon of the secretaryship was received with regret and thanks for his able services during the past two years. The following were elected to fill the various offices:—President, Mr. R. Gore Gardner; vice-presidents, Messrs. A. J. Craston and E. H. Young; treasurer, Mr. A. Bird; hon. secretary, Mr. H. C. Bird, 91, Whittington Road, Bowes Park, N.; hon. assistant secretary, Mr. F. W. Slater, jun.; librarian, Mr. C. S. Carr; Council, Messrs. W. E. Hughes, F. C. Hornsey, A. Kernon, A. Hawes, J. T. Smith, H. Oliver, and W. H. Drifill. Votes of thanks were passed to the retiring officers and Council, lanternists, auditors, and scrutineers.

NORTH MIDDLESEX PHOTOGRAPHIC SOCIETY.

On January 18, at the Hanley Hall, Crouch Hill, Mr. M. Fraser Black lectured on "Gaslight Papers." As a standard of this class of paper, without making any invidious distinctions, Mr. Black took Velox, pointing out the adaptability of the various brands to the different classes of negatives. For the purpose of demonstration, Mr. Black exposed negatives of varying densities by means of magnesium ribbon, taking for an average negative on to Art Velox 1 in. and 2 ft. distance. He developed with the M.Q. prepared developer and fixed in an acid bath. In order to ensure the even flow of the developer he put his prints into a preliminary water bath. As an alternative developer

he recommended Rodinal of the strength 1:20 and fixing in a plain hypo. bath. He recommended quick development. The print is to be taken out of the bath as soon as an image becomes visible and carefully watched for correct density, and as soon as this stage is reached is plunged into the fixing bath.

CROYDON CAMERA CLUB.

JANUARY 18.—Mr. F. C. Wardall, representing Messrs. Zeiss, gave a most instructive lecture entitled "A Large Aperture." The lecture, as a matter of fact, went considerably beyond what the title indicated, and resolved itself into a very complete exposition of the principles underlying the constructions of lenses, their various aberrations, and the methods employed for correcting such. The important advances rendered possible by the labours of Professor Abbe and Dr. Schott, leading to the introduction of the Jena glasses, were clearly explained, and it was pointed out that lenses could now be obtained, for all intents and purposes, free from spherical aberration, astigmatism, and the secondary spectrum, together with a high intensity, great covering power, and a flat field. With a perfectly corrected lens, Mr. Wardall said, stopping down would not improve the definition, though this might be necessary to obtain sufficient depth, and by means of diagrams he showed that with a large aperture a photographer of necessity was working under restricted conditions, owing to the so-called depth of focus being so limited. Under these conditions, for optical reasons, a short-focus lens was an advantage. The lecture terminated with a series of lantern slides showing the various scientific instruments manufactured by Messrs. Zeiss, and the magnificent premises and works of the "Carl-Zeiss Stiftung" in Jena. Its great originator, Mr. Wardall said, with evident feeling of sorrow, was no more, Professor Abbe having died on the 14th inst.

In the short discussion which followed, Mr. E. A. Salt said he doubted whether the suppression of the secondary spectrum was of any material benefit in ordinary landscape and similar work. He would also like to have Mr. Wardall's opinion as to whether the theoretical objections to correction by air spaces were borne out in practice.

Mr. C. E. Kenneth Mees paid a warm tribute to the late Professor Abbe, and alluded to the scientific and social scheme worked out by him for Zeiss as a remarkable achievement and a model for the whole world.

Mr. Wardall, in reply, thanked Mr. Mees for his kind words. As to the correction of the secondary spectrum, he agreed with Mr. Salt so far as he went. Its suppression was, however, of the greatest importance in copying and process work, for here the fringes of colour in a lens not so corrected would undoubtedly impair definition. In landscape work it was a case of great reduction, and was not of importance. The possible disadvantages in lenses having three or more separated components were the creation of extra-axial foci and flare, with a small stop. Both of these objections rarely became apparent in practice.

SOUTHAMPTON CAMERA CLUB.—The principal item in the meeting of the members of the above, held on Monday, the 23rd inst., at the club-room, was the exhibition of the prize slides in the "Photographic News" competition. These received the warm appreciation of the members, which they merited. An exhibition of members' slides followed, and the transaction of club business concluded the meeting.

HILLSBORO' and District Photographic Society spent a very enjoyable evening on January 11, when Mr. W. F. Slater, F.R.P.S., gave a very interesting and instructive lecture on "Photographic Lenses," and demonstrated Messrs. R. and J. Beck's novelties, among which were "The Unofocal Anastigmat Lens," "The Zambex," "Dai-Cornex" and "Telephoto Hand Cameras," and the new shutter-testing apparatus.

News and Notes.

A REJECTED Whistler Picture.—The International Society of Sculptors, Painters, and Gravers have just heard by cable from their representative, now in New York, that he has secured for the forthcoming Whistler Memorial Exhibition at the New Gallery "The Large White Girl," owned by Mr. Whittemore, of New Haven. This is the picture painted by Mr. Whistler in the early sixties and rejected at the Salon of 1863, but later shown in the Salon des Refusés, along with works by Manet, Fantin Latour, Bracquemond, and others. At the close of the exhibition the picture was sent to the United States, where it has since remained. It was lent for some time to the Metropolitan Museum, New York; since then it has scarcely been seen.

An interesting function took place on Thursday, January 18, at the Wellcome Institute, Dartford. On the invitation of Messrs. Burroughs, Wellcome, and Co., a convention of continental and district managers of the National Cash Register Co., journeyed to Dartford to inspect the club houses, gymnasium, baths, and sports-fields, etc., which form part of the scheme for the social and physical advancement of the employees at Dartford, provided by Mr. Henry S. Wellcome. The National Cash Register Co. in America is distinguished by similar philanthropic activities, and after dinner in the club house an illustrated lecture, showing the work now being done at the N.C.R. factory, was delivered to an audience of over 500 staff and employees of Burroughs, Wellcome and Co., in the club assembly rooms. The visit, like the movement, is one of good omen for the happier relations of employers and employed throughout the civilised world.

THE Photographic Exhibition at Earl's Court, to be held from March 16 to 30th, has already been announced in our columns. The full preliminary prospectus has now appeared, and is obtainable from the organising managers, 119-125, Finsbury Pavement, London, E.C. As stated in the prospectus the president of the exhibition is the Hon. H. L. W. Lawson, J.P., and the vice-presidents, James Cadett, E. Sanger Shepherd, J. T. Ashby, Carl Hentschel, and Georg Fritz. The exhibition will be divided into the following sections:—(1) Photographic Appliances and Material. (2) Pure Photography (Professional and Amateur). (3) Photographic Appliances for Reproductive Processes. (4) Art and other Illustrations having a Photographic basis. (5) Picture Postcards in real Photography and by Phototype Processes. (6) Some Methods of Reproduction (Printing) demonstrated. A series of competitions have been planned by Mr. H. Snowden Ward, and will be judged by him in collaboration with Mr. A. Horsley Hinton. The scheme of these competitions will be as follows:—Classes open to all Photographers: (1) Landscapes and Seascapes. (2) Architecture (interior and exterior). (3) Portraits. (4) Figure Studies and Figures in Landscapes. (5) Any other class of subject. (6) Set of six Prints suitable for Pictorial Postcards, with title for each card, and title, with or without short descriptive note, for the set. The terms for picture postcard rights of reproduction to be stated on entry form and in catalogue. Professional Classes: Open only to Professional Photographers in business for themselves, or assistants who have been engaged in bona fide professional work for at least two years. (7) Portraits. (8) Technical Photography (machinery, workshop interiors, photography for advertisements, etc.). (9) Studio group. (10) Outdoor group. (11) Set of half-dozen Local Views not larger than whole plate. An entrance fee of one shilling will be charged for exhibits in each class, and all parcels must be sent, carriage paid, to the Organising Managers, Photographic Trades and Art Exhibition, Earl's Court, London, S.W., on any day in the week previous to the opening, but not later than March 14. A series of lectures and demonstrations are arranged for, among which are Mr. Sanger Shepherd, on Colour Photography, Mr. William Gamble, on Process Engraving, and Mr.

A. J. Newton, on the work of the L.C.C. School of Photo-engraving and Lithography, of which he is principal.

Commercial & Legal Intelligence

CONTINENTAL Warwick Trading Company, Limited.—The above company has been registered with a capital of £5,000 in £1 shares. Object, to acquire and deal with patents and inventions, to develop and turn to account the same, and to carry on a business not particularly described. No initial public issue. The subscribers are to appoint the first directors. Qualification, 100 ordinary shares. Remuneration (except managing director) £50 per annum, divisible. Registered office, 4 and 5, Warwick Court, High Holborn, W.C.

SARONY AND Co., LTD., has been registered with a capital of £5,000, in £5 shares, to acquire the Sarony Studio, Scarborough, and other businesses. The subscribers are:—S. W. Fisher, photographic artist, Scarborough; F. P. Reifenedy, artist, Harrogate; A. O. Fisher, photographer, Scarborough; V. Fowler, J.P., Scalby; J. Linn, art dealer, Scarborough; J. W. Bailey, York; J. Tonks, J.P., Scarborough—one share each. No initial public issue of shares; £4,000 6 per cent. mortgage debentures are offered for public subscription. The first directors are S. W. Fisher (chairman and managing director), S. M. Hudson, A. O. Fisher, and F. P. Reifenedy. Trustees for debenture holders, J. Pirie, J.P., 105, Castle Road, Scarborough. Registered office, Sarony's Studio, Sarony Square, Scarborough.

A COPYRIGHT Photo of Sir Henry Irving.—In the Court of Session, on the 19th inst., Lord Ardwall closed the record in two actions brought by William Crooke, photographer, 103, Princes Street, one against the Scots Pictorial Publishing Company, Ltd., 180, Hope Street, Glasgow, and the other against W. Hodge and Co., 34 and 35, North Frederick Street, Glasgow, and North Bank Street, Edinburgh, the publishers and printers respectively of the "Society Pictorial." In April, 1904, the pursuer took a photograph of Sir Henry Irving, and registered it in his own name as proprietor of the copyright, and he complains that on November 12 there was published in the "Society Pictorial" a picture of Sir Henry, which was a copy or colourable imitation of the copyright photograph. Damages to the extent of £2,000 are claimed in each action. The defenders state that the photograph of Sir Henry Irving by the pursuer was taken at the request of "The Sphere," in which it was subsequently reproduced, and that an advance agent of Sir Henry Irving's company supplied the defenders with a copy.

RE FRANZ BAUM.—This debtor, a photographer in Deansgate, said he started business in 1872. He had a deficiency of £322 on liabilities of £347. All his furniture and photographic apparatus was assigned to his wife in consideration of an advance of £75. The debtor said his wife had formally taken possession of everything. The debtor said that he was now using the apparatus as the agent of his wife. He spoke of very bad trade during the last four years. At first the war was to blame, and afterwards the depression in the cotton trade, and later still the weather. "People will not come out to have their portraits taken in such weather as we have been having lately," he said. "It is no use telling them that we use the electric light; they won't come out." Because of bad trade the gross takings last year were only £502, one quarter of what they had been in some years. The debtor denied that there was any real value in the goodwill of a photographer's business. The renewal order on old negatives did not pay for storage. He once gave £150 for 100,000 negatives, and it was the worst bargain he ever made. He would have been glad a month later to sell the lot for £5. In the last two years Stock Exchange speculations had involved him in a loss of £300. The examination was adjourned.

Correspondence.

- * * *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given*
- * * *We do not undertake responsibility for the opinions expressed by our correspondents.*

THE ROYAL PHOTOGRAPHIC SOCIETY.

To the Editors.

Gentlemen.—I have much pleasure in handing to you the enclosed report of a meeting held in the library of the R.P.S. on Friday last, when the members present expressed a hope that you would kindly assist them in making known the result of their deliberations.

Your good services in this direction will be greatly appreciated.—
Yours truly,

C. CHURCHILL.

180, Victoria Road, Old Charlton, Kent.

Appended is the report of the meeting. In asking us to publish it, Mr. Churchill, we fear, exposes himself and others to criticism, because, if we are correctly informed, a number of those for whom support is asked were present at the meeting. That fact, however, need not prevent R.P.S. members from supporting any or all of the nominees on the ground of their past records of service to the society or their promise of future usefulness.

"The election of President and Council of the R.P.S. appears to be causing more than the usual amount of interest on the part of the members, so much so that on Friday last a meeting was held, at which the question was discussed at some considerable length. The unanimity of those present was remarkable, and it was decided to promote the candidature of the following gentlemen for office. President: General Waterhouse. Vice-Presidents: Sir W. Abney, The Earl of Crawford, T. R. Dallmeyer, J. S. C. Mummery. Council: A. W. W. Bartlett (late secretary of society), H. W. Bennett*, St. L. Carson, C. Churchill*, Leslie Clift, Douglas English*, T. E. Freshwater*, F. Ince, Dr. Lindsay Johnson, G. Lamley*, Furley Lewis, Southcomb May, J. S. C. Mummery*, J. Borthwick Panting*, C. H. Oakden*, Leslie Selby, Sanger Shepherd*, C. W. Somerville*, B. Gay Wilkinson*. Note:—The * denotes Fellows of the Society, of whom half the Council must be formed.

The reference to the re-establishment of the office of hon. secretary, made in the late Presidential address, came in for very keen criticism, and the meeting recorded their opinion that the resuscitation of the honorary office was undesirable, and that the secretary should be directly responsible to the Council by whom he is appointed.

From the tone of the meeting there is no doubt that any proposal to appoint an hon. secretary will be strongly opposed at the annual meeting.

It was incidentally mentioned that the Council had very considerably strengthened the office staff during the past two years, to enable it to efficiently cope with the large amount of work it had to perform.

It appears that although the Reform Committee of 1902 has given no sign of existence during the past two years, it needs but little to bring it again into activity, and make its force felt in endeavouring to raise the status and membership of the parent society."

THE FOCAL PLANE SHUTTER, ETC.

To the Editors.

Gentlemen.—At page 45 of current issue, re "Focal Plane Shutters," the argument dealing with efficiency I consider to be untenable. The author says that "between F and G the plate receives the full action of the lens." That is quite right. On the adjacent portions EF and GH he says, "the action is incomplete," thereby implying that the light falling on FG is spread out, and thus reduced in intensity. But these portions do not receive the image of the central part, but the vanishing images of those portions of the view that adjoin it, and therefore cannot lower its light value. Thus I think that the argument is wrong.

For years I have been endeavouring to combat the idea in Process Work that the dot under any one screen opening is due to any light other than that derived solely from that minute portion of copy which it represents. The case in question is very similar, as is proved by the first formula quoted.—Yours etc.,
J. A. C. BRANFILL.
West Dulwich, S.E.

THE MARKING OF APPARATUS.

To the Editors.

Gentlemen.—We should like, through the medium of your journal, to bring before the manufacturing portion of your readers a subject which we think must be considered a matter of some importance. We were asked within the last week to fit an Iris diaphragm to a photographic lens bearing the name of one of the oldest of our English lens manufacturers. The mount had been cut through for a "between lens shutter," and our estimate for the cost of fitting "Iris" and preserving the old mount was considered too high by our customer. We were told that we had better make a "new mount," as it would be cheaper. We explained that this would entail the engraving of the maker's name on the new mount and we declined to do this.

Our customer (who is a well-known photographic dealer) seemed to consider our scruples very absurd, and stated as a positive fact that he could get done what we had declined to do by a most respectable man having business relations with all the best houses in London.

We should like to ascertain the opinion of the manufacturers as to what they think of this statement of the existence of a man who is prepared to place the name of anyone on a piece of work executed by himself.

There is no need for us to dilate upon the facilities thus afforded to unscrupulous traders to create two expensive instruments out of one. The possibilities are enormous if it is to be considered a recognised thing in the trade that a man has a right to engrave or mark apparatus with any other name or trade mark than his own, except, of course, with the special permission of the owner or owners of such name or trade mark.—We are, yours faithfully,

PERKEN, SON AND CO., LTD.,

E. T. Perken,

Director.

THE EXHIBITION OF THE BELGIAN AMATEUR PHOTOGRAPHERS' CLUB.

To the Editors.

Gentlemen.—The annual exhibition of the Club d'Amateurs Photographes de Belgique will be held at their club-house, 12, Rue Aux Choux, Brussels, from 18th to 30th March, 1905.

This is one of the important exhibitions of photographic art in Belgium, and any English amateurs visiting Belgium during the exhibition time will be heartily welcomed.

Will you kindly bring this matter before the notice of your subscribers.

Thanking you in advance and always at your service, I remain
yours faithfully,

HERBERT J. HIGGS.

LOSS OF GOODS.

To the Editors.

Gentlemen.—We find as the result of the interchange of several telegrams with one of our Scottish customers that the reason for the non-delivery of a parcel of negatives which he posted to us on the evening of the 18th inst. is that the mail basket containing the parcel was destroyed by the fire which followed the regrettable accident to the Midland Scotch Express on the morning of the 19th inst. Fearing that the parcels of other friends in Scotland and the North of England may have been thus destroyed, and thinking also that the information may be of service to other London business houses, we venture to ask the favour of the insertion of this letter in the columns of your valuable Journal as the readiest means to communication with the profession and the trade generally.—Yours faithfully,

RAINES AND CO.

Ealing, W.

Answers to Correspondents.

* * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

* * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

A. Lamb, 18, Gowthorpe, Selby, Yorkshire. Photograph of W. Ozley.

W. R. Fergus, Anworth Villa, Dumoon, Scotland. Three Photographs of Canon A. Taylor.

H. Dunning, Bridge Street, Usk, Mon. Photograph of Brynderven House, Bettws Newydd.

J. B. S.—See Photo-mechanical Notes, p. 71.

STUCK.—See answer to Arthur Griffiths.

A. L. K. (Leeds).—Thank you, but the offer is not one we can accept.

E. A. CARNELL.—Many thanks for the cuttings and your kindly offer, but we cannot avail ourselves of the latter.

D. G. THOMAS (Wrexham).—The firm is still at the address you name. We should advise you to write again.

H. B. BOYD.—Possibly the Aerograph Company, 30, Memorial Hall Buildings, Farringdon Road, E.C., would do the job for you.

A. W. RICHARDSON.—We cannot answer questions on publishing matters. Better write to one of the journals which offer aid to literary aspirants.

RADVOUS HANNA (Assiout).—We have asked a publishing firm to supply you the book, as our own publishers do not supply books. We are obliged for your suggestions, which we will bear in mind.

ALPHA.—A camera of the make you name will answer well for the special work, but we think you will be wise to choose a lens of greater covering power. This you may select from the numerous anastigmats of the leading makers.

WORKING UP ENLARGEMENTS.—Please tell me where I can obtain a book on working up enlargements (bromide) with crayon or pencil—a book suitable for beginners.—L. B. H.

The best book is the "Art of Retouching Negatives and Finishing and Colouring Photographs," by Robert Johnson. Price 2s. from Marion and Co.

REGISTERING TRADE MARKS.—Will you please inform me of the name of a firm which undertakes to register trade marks? I cannot find one in the ALMANAC. G. H.

You should apply to the Patent Design and Trade Marks Office, 25, Southampton Buildings, Chancery Lane, London, at which you can effect the registration by post.

GLAZING PRINTS.—Could you also inform me through your medium a good preparation for glass previous to glazing prints?—G. H. M.

Beeswax, 20 grains in turpentine, 1 ounce; or spermaceti wax, 20 grains in benzole, 1 ounce. A few drops of either solution are rubbed over with a bit of flannel, and the glass then polished with a piece of silk rag.

MAKING BLOCKS.—I shall esteem it a favour if you will kindly let me know the name of book which gives instructions for producing designs on copper for engravers' use, and where to obtain same. APROPOS.

We presume our correspondent means half-tone blocks. If

so, the half-tone process by Julius Verfassser, price 5s., published by Iliffe and Son, is the best work.

P.O.P. NEGATIVE.—Will you kindly tell me if it is possible to wax a negative made on P.O.P. paper (gelatino chloride)? I want it for the purpose of improving the results of a bad negative. Have tried beeswax and turpentine, also beeswax and benzol, rubbed on, but the results are not uniform, and printing through the opaque paper this weather is very slow.—PRINTER.

As nearly all gelatine P.O.P. is coated on paper which bears an emulsion of barium sulphate, it is almost impossible to render it transparent. We would suggest that albumen or a plain paper be used, as there would be no difficulty in making these transparent. Very thin bromide paper could also be used.

RETOUCHING BROMIDES.—I should esteem it a favour if you would kindly give me a little further information on "The Rapid Retouching of Bromides" article in B.J.P. January 13, 1905. (1) To what dealers should I apply for the pastels, etc.? (2) How is the picture glazed? Could you advise me as to whom I should go for lessons in this method of working up bromides? Thanking you in anticipation.—ARTHUR GRIFFITHS.

(1) Messrs. Reeves and Son, 53, Moorgate Street, E.C., supply soft French pastels suitable for working up enlargements. (2) The word "glazed" refers to placing the picture under glass—i.e., framing. We believe lessons are given in similar methods of working up at the Polytechnic, and there is also postal instruction available.

FLASHLIGHT.—Would you kindly advise me the easiest method for taking a flashlight photograph of a large room with a party of about 100 heads; also quantity of powder used, and how many lots used for each exposure; and if an ordinary outdoor camera, would do for same; and what lens, wide angle or landscape; or any other particulars you may suggest?—A. WALKER.

The flash powder should be arranged in a train, being laid in a shallow trough of thin sheet iron. The higher it is placed (with due regard to the safety of the ceiling) the better. It is not easy to prescribe quantities, but try $\frac{1}{2}$ to 1 oz. of powder laid in two lines of 18 in. wide, and using an extra rapid plate and lens at $f/11$. Your ordinary camera and lens should answer.

OLD LENS.—Can you kindly inform me, re lens enclosed herewith, (1) Size picture it will cover, say C.D.V., Cabinet, 1.1, etc.? (2) What would be the present value of it? (3) Is it a very old-fashioned one, and the probable make? (4) The glasses of the lens being concave one side and convex the other seems quite different to some in use now. Why is this, and what is the advantage.—LENS.

(1) The lens is about 15 inches in focal length, and will cover a very large plate of about 30 by 20 inches. (2) Its value at the present time is practically nil. (3) The lens is the old globe lens of Harrison and Schnitzer, New York, and dates back to 1862. (4) The outside deep curves, which, as mounted, form a sphere, gave great covering power, but the construction suffers from spherical aberration and flare.

LENS.—I have a cheap Euryscope that gives a double image of any bright object, as a window in interiors, further down on the plate, or else in the roof. What is this fault? No hole in bellows. Also, in focussing a gas jet, with Euryscope on one side of the focus screen, a weak, ghostly image of the jet is seen on the other side. An R.R. shows the same trait, and when the eye is placed at the point where the ghostly image appeared on the screen (screen removed) the whole lens seems

lit up like a lantern condenser. Is this natural or faults in lenses.—OTHELLO.

It is almost impossible to do away with the secondary images, which are technically known as "ghosts," but they should not be so distinct as to form real images at the plane of the plate. Frequently, when a rectilinear lens is focussed on a candle flame, eight ghosts may be seen. Our advice would be to dispose of the lenses and purchase one of the newer and more costly, and also more perfect, anastigmats.

FIXING WORKED-UP ENLARGEMENT.—What is the best method of fixing an enlargement after it has been worked up in chalk? I have noticed in cases of chalked enlargements a beautiful gloss. Is this caused by any fixing medium? Of course, I do not refer to fixing the photograph, but the fixing of the chalk, so that it may not rub off or otherwise be spoiled.—CARBON.

A special varnish known as fixative may be obtained from most artists' colourmen, but a somewhat similar varnish may be made from—White lac (fresh), 1 ounce; methylated spirit, 4 ounces; absolute alcohol, 2 ounces. The enlargements should be placed face upwards on a table or other flat surface and the clear solution of the above sprayed over it with an ordinary scent spray diffuser, which must not be held too near the paper. It is quite possible also to "fix" the chalk or crayon by holding the enlargement over a dish of boiling water so as just to soften the gelatine, but it is a ticklish job.

BROMIDE PAPER.—In furtherance of some experiments I am making I have some bromide photographs in black and white (i.e., there are no half tones). Is there any method by which I can remove the emulsion in the high lights, leaving the bare surface of the paper exposed? Thanking you in anticipation.—H. SEYMOUR.

The best plan would be to adopt Howard Farmer's method, which was suggested by him in 1894. If a plate or paper, after developing, fixing, and washing, be immersed in a 20 per cent. solution of ammonium bichromate, the gelatine in contact with the bichromate becomes absolutely insoluble, and the gelatine, where there is no silver, can be washed away just as in a carbon print. Farmer used ferrous oxalate as a developer, and for the success of the process it is obvious that the developer used must have no tanning effect on the gelatine; but as practically pyro is the only developing agent that does tan this should not present any difficulty.

THE H. and D. SYSTEM.—I should be greatly obliged if you would kindly give me any information concerning the Hurter-Driffield system of testing the speed of dry plates. Should I be making too much demand upon your valuable space, perhaps you would kindly tell me where I can get such information.—ARROW.

Briefly, the Hurter and Driffield system consists of exposing a plate to a constant light for definite periods of time each of which is exactly double the preceding one, developing with a standard developer at a standard temperature, fixing, washing, and drying, and then reading the densities in a photometer and plotting the same on a chart, and from this finding the inertia, which by a simple calculation gives the speed of the plate. The whole of the necessary apparatus can be made at home or bought commercially, and a detailed description of the process by Mr. Driffield will be found in No. 56 of the "Photo Miniature," price 6d.

WORKING UP ENLARGEMENTS.—Will you please let me know if the black and white stumping chalk used for working up enlargements is the most favoured method employed by photographers? I shall be pleased if you will tell me this, or of any improved method.—J. R.

(1) Artists in finishing enlargements employ many methods and mediums. Chalks, crayons, water colours, pastels, and oils are all brought into requisition according to the nature of the order. (2) For quick finish the Aerograph is being widely used, and a free demonstration of its rapid effects can be seen at the office of The Aerograph Co., Ltd., 30, Memorial Hall Buildings, Farringdon Street, London, E.C. The Aerograph has rendered possible the cheap finishing of enlargements that previously could not be done by hand labour at anything like the same cost. The highest-class enlargement artists use the Aerograph sparingly at present, for the hand wielded brush, crayons, etc., must always be the most artistic. The Aerograph is necessarily more mechanical, but for quick finishing and beautiful effects of gradation it is unsurpassed, and the machine has "come to stay." If your knowledge is limited you should take lessons in B. and W.—our miscellaneous columns contain the names of several teachers—and also you will find some other announcements on page 28 in "The British Journal Almanac," 1905.

P.O.P. TONING AND ENAMELLING.—Some time ago I copied out of the B.J. the following: Dr. Liesegang's toning bath—Chloride of gold, 1 g.; carbonate of soda, 15 g.; chalk, 5 g.; water, 1 litre. After twelve hours the bath is perfectly clear and colourless, when it is ready for use. It is very durable, and gives fine tones. Please to say if the above bath is for P.O.P., and what colour tones it gives. Will you also kindly say how to properly enamel P.O.P., not merely squeegeeing? H. GREEN.

The above bath may be used for P.O.P., and it gives from brown to purplish blue tones, according to the duration of toning. The prints must not be left in too long, otherwise they become quite blue, and as they turn rather colder as a rule after fixing, this must not be lost sight of. The bath is really very strong; about four times the ordinary strength. To enamel P.O.P. prints, take a sheet of glass and clean well and polish with French chalk, then coat with enamel collodion, such as: Pyroxline, 7 gr.; alcohol, $\frac{1}{2}$ oz.; ether, $\frac{1}{2}$ oz. As soon as the collodion has set, slide into a dish of water and rock till all greasy marks have disappeared, then transfer to another dish containing a solution of gelatine in water, 5 gr. to 1 oz., this must be just warm enough to be fluid. Immerse the prints face downwards, and after a minute or two soaking bring the print and glass into contact, squeegee well, and then rear up to drain and dry; when thoroughly dry, lift by one corner, or cut round the edges and strip.

NOTICE.

A number of "Answers to Correspondents" are crowded out of this issue, and will appear next week.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

The British Journal of Photography.

The Oldest Photographic Journal in the World.

ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWOPENCE.

TERMS OF SUBSCRIPTION. Post Free (UNITED KINGDOM AND THE CHANNEL ISLES).

	s. d.	
One Year	10 10	France, Belgium, United States, Canada,
Half Year	5 5	Australia, Africa, New Zealand, New-
Quarter Year	2 9	foundland, Germany, Russia, Portugal,

EX CATHEDRA.

Accessions to the Scottish Federation. We are glad to hear that one outcome of the exhibition of the Scottish Salon has been the addition of two more societies to those enrolled under the Scottish Photographic Federation. Crieff Photographic Association and Edinburgh Photographic Club are the new-comers, and the latter should strengthen the ranks of the Federation as its membership includes such leading workers as Crooke, Moffat, and Patrick, and others.

* * *

The French Salon. They still order some things better in France. The Photo Club of Paris, for example, holds its annual Salon in the height of the season and in the Palais des Beaux Arts in the Champs Elysées. The tenth exhibition will be opened on May 10, and will remain open every day from 10 to 6 until June 19. Lest these dates may deceive would-be exhibitors we would hasten to say that no exhibits are received after April 10, and that entry forms should reach the Photo Club at 44, Rue des Mathurins, Paris, as early as March 1. No prizes, medals, or commemorative plaques are offered, and no charges are made for wall space. But the committee take the wise course of limiting the works of any exhibitor to six, though a greater number, of course, may be submitted.

* * *

The R.P.S. Election. A correspondent calls attention in this week's issue to what is, we hope, but an accidental omission in the list of candidates recommended in the report forwarded to us, and which appears on p. 78 of our last issue—namely, the omission of any pro-

fessional photographer's name. It has been frequently pointed out in the past that the R.P.S. has neglected its professional members, and we cannot quite see why they should not be represented on the Council, considering that they have as big a stake in the success of the Society as its amateur members. If we are correctly informed, fifteen of the specially recommended candidates were present at the meeting in the library, and there were only three or four outsiders, so that the truth is that the pronunciamiento is practically a personal canvas by these members. We have nothing to say against the candidates, only the report may give a much stronger colour to the agitation than it deserves.

Chemical Action on Gold.

The reputation which gold enjoys as the most unalterable of metals is being undermined by the researches of a number of chemists. A review of recent work, and a description of some new experiments appear in a paper by Victor Lenher, in a recent issue of the Journal of the American Chemical Society. The chemicals which attack the noble metal run into quite a long list. They cannot be said to suggest any direct photographic applications, but it may be well to mention the chief of them in the hope that use may be found for them in gold-toning or in the reduction of over-toned prints. It is probable that many of the re-agents which the chemists have found to attack ordinary metallic gold only with the aid of heat or in a very concentrated solution would have action on the finely divided metal as it is found in a toned print under possible photographic conditions. The metallic perchlorides, perbromides, and periodides, hot selenic acid, and even alkaline sulphides and thiosulphates are distinct solvents of gold. In the case of selenic acid, auric selenate is formed, and it has been found that a similar action takes place in the case of the analogous telluric acid. Both these bodies probably obtain their solvent powers from the disengagement of oxygen when their solutions are heated, and this fact has led to the discovery that a number of mixtures capable of supplying oxygen possess action on gold. Among these are manganese dioxide and sulphuric or phosphoric acid, and potassium permanganate with either of these acids. Lastly, electrolytic oxygen formed as an anode of gold in presence of sulphuric acid, or an alkaline electrolyte rapidly effects the solution of the metal.

* * *

Studio Construction.

If one policy more than another has been pursued by the best photographers it is the re-modelling of the studio in a way to rob it of all resemblance to the conventional bare apartment littered with obvious "accessories," and suggesting the want of comfort, if not actual discomfort, on the first

entrance. In this revolt from the old order of things the photographer has received powerful aid from makers of plates, lenses, and artificial light, yet it may still be doubted whether half of the power thus afforded them has been applied to the reform of the studio. Make your studio like an ordinary room and you have gone half way to putting the sitter at ease. In that task attempts have been made to oust the strong top-light from the scheme of lighting, or rather to place it so that it will not seem anything out of the ordinary. In many cases these designs are forced upon the photographer by the premises in which the studio is to be, but none the less they have had the desirable result of disguising the studio as a salon. We are reminded of this movement towards the perfect studio by the reproduction in a German year-book of the atelier of Grainer, of Munich, which is lighted chiefly by a row of windows down the right-hand side of a spacious apartment. The ceiling is flat, and contains a large glazed space which can be curtained or uncovered at will, though it is stated that, except for groups and full-length figures, the side-lights alone are used. The room can thus be furnished from floor to ceiling strictly to carry out a given scheme of furnishing, and if it is possible to instal artificial light as the provider of the illumination overhead, the photographer may prepare to descend from the inaccessible heights of the fifth or sixth floor to the ground level or the first floor.

A New Mercury Lamp.

Dr. O. Schott recently exhibited and described before the Society for Natural Science at Jena a modification of the old form of Aron's mercury lamp, to which reference is made by Mr. Gamble in his paper on page 85. In Aron's original lamp, which was something like an inverted U, the mercury itself formed the arc, as each arm was nearly filled with mercury, and the lamp was tilted till some ran from one arm into the other, and so formed connection between the two poles, which were platinum wires sealed into the bottom of the arms and covered by the mercury. In the new lamp, the poles are ordinary carbon, but the most important improvement is in the nature of the glass of which the lamp is made. The old glass, even when only 0.1 m.m. thick, absorbed the ultra-violet, but the well-known Jena glassworks with which Dr. Schott is connected have succeeded in making a glass that is transparent to the ultra-violet even to λ 235 μ . The new lamp, which has been called the Uviolamp, is specially suitable for photographic work and for all purposes in which the ultra-violet rays are important, as in testing new dyes as to their fading properties and also as a substitute for the expensive Finsen light. For special optical work Gumlich in 1897 employed a mercury-cadmium amalgam instead of pure mercury, but from some unknown cause this lamp was extremely liable to fly to pieces. Now Lummer and Gehecke have succeeded in making a lamp of amorphous quartz in which the mercury-cadmium amalgam can be used without so far any apparent liability to sudden fracture, but it does not yet seem practical, as, either from occluded gas or other cause, it was found necessary to again exhaust the lamp after some use. Cadmium gives several bright red and orange lines which modify the ghastly effect of the pure mercury lamp, and it is quite possible that other amalgams might be found useful in this direction.

* * *

Fallacies of Photography by Rule.

Among the cases of false counsel which follow from the inconsidered application of a general law there are none more frequent than those involving the well-known law of in-

verse squares which governs the diminution of light. This law, that the illumination of a surface varies inversely as the square of its distance from an illuminant, holds good only when that illuminant is a point. If a light is spread over any considerable area, the illumination ceases to follow the law, and as the illuminants, lamps and gas flames, commonly employed by photographers, are usually large compared with the surface they illuminate, the law is more often honoured in the breach than in the observance. In instructions for printing on bromide or "gas-light" paper, for example, it is often advised that the exposures should be timed in accordance with the law regardless of the fact that the source of light is a gas flame, perhaps two inches in diameter, and is only a few inches from the sensitive paper. But it will be found that under these conditions the exposure at double the distance will not need to be nearly as much as the full four times deduced on false premises from the law of inverse squares. The latest instance we have noticed of this oft-repeated fallacy is the attempt of a German writer to systematise flashlight exposures, or rather the weights of flashlight powder, which should be used for subjects at different distances from the light. It is suggested that the powder should be weighed out on the basis of the law of inverse squares. Even setting aside the differences between a small dose of powder and a large one as regards its complete combustion—which is a considerable disturbing factor—the fact of the illumination proceeding from a source of the area of a flashlight will upset any calculation based on the "inverse squares" rule. And flashlight photography of subjects which differ enormously in the actinic value is a particularly unfortunate sphere in which to look for success in reducing correct exposure to a rule-of-three sum.

THE "ANCIENT LIGHTS" QUESTION.

A CASE that may prove of considerable interest to photographers who at some future time find their studio lights interfered with by the erection of new buildings came before the Law Courts a week or so ago. A brief report of the case will be found on another page. Until quite recent times it was recognised in law that windows that have had an uninterrupted light for twenty years enjoyed what is known as "ancient lights," and that the light coming through them must not be obstructed by any new buildings that may be erected in the neighbourhood. This question in the past has been settled over and over again in the Law Courts. In fact, the subject of ancient lights has always been a fruitful source of litigation. The chief points, however, have usually been with regard to the angle at which the light was interfered with. So far as we can remember, no question was ever raised as to whether, notwithstanding the obstruction, there was still sufficient light left for the owner's business. It was always understood that, whether he actually required it for his business, or not, he was entitled to the whole that he enjoyed as his "ancient lights," and we know of more than one or two cases where photographers have received very substantial compensation for their light being obstructed by new erections. Within the last three or four years we know of a case in which a provincial photographer recovered considerably over a thousand pounds by way of compensation for obstruction of light from his studio.

It has just been said that up to quite recently the dictum that ancient lights must not be interfered with by new buildings has always been upheld; but last year this was somewhat modified in the case of the Home and

Colonial Stores v. Colls. In this case the plaintiffs sought to have some new buildings the defendant had put up pulled down. The case was tried by Mr. Justice Joyce, and it was not contended that the new buildings did not obstruct some of the plaintiffs' light, but that the amount of light left was sufficient for the plaintiffs' business. This contention the learned Judge upheld and decided against the plaintiffs. The plaintiffs then took the case to the Court of Appeal, and here the judgment of Mr. Justice Joyce was overruled, and the appeal allowed. Next the defendant appealed to the House of Lords, and here the judgment of the Court of Appeal was reversed, and that of the lower Court upheld. The Lord Chancellor, in delivering judgment, remarked that if the respondent could restrain in the way he thought he could, and the Court of Appeal had decided he could, towns could not grow, and expansion would be unduly restricted. In the end judgment was given for the appellant with costs, and costs in the Courts below. This is the first case, we believe, in which such a judgment has been given, and as it was given by the House of Lords, of course it stands as a precept in all future cases.

The case referred to at the beginning of this article is perhaps one of still more importance to photographers than that just quoted, inasmuch as it involves the question as to whether a person is entitled to any greater amount of light for the purpose of carrying on his business than another person. It appears that the plaintiff, a Mr. Ambler, of Leeds, sought damages from the Bishop of Leeds on account of light obstructed by the new Roman Catholic Cathedral. After some negotiations arbitration was resorted to by the parties. In the result the arbitrator

found that, in spite of the building, there still remained sufficient light for all ordinary purposes, and that the plaintiff was not entitled to damages for interference, but, if a Court of Law found that he was entitled to an extraordinary amount of light, he assessed the damages at £600 odd. In the course of the hearing of the case in Court, it was argued for the plaintiff that user for twenty years and the nature of his profession entitled him to a special amount of light. This the learned judge, Mr. Justice Bray, ruled was not so, and held that a person carrying on a delicate trade was not entitled to a greater enjoyment of light than other persons, and therefore he gave judgment for the defendant.

It will be noted that, according to the report of the case as it appeared in the daily papers, no one person, whatever his profession may be, is entitled to more light than another, although he may enjoy "ancient lights." In the case of the Home and Colonial Stores, it was ruled that enough light was left them for their business—that of provision dealers. Of course, architects require a good light for their work, particularly as some employ photography for reproducing their drawings—say, by the blue process. In the case now under notice it is clear that the architect's light had suffered very materially by the new building, otherwise the arbitrator, subject to the question of law, would not have awarded the substantial damages he did. It is needless to say that photographers require far more light for their work than do architects. In face of these two recent judgments we cannot but congratulate those photographers who in the past have obtained substantial compensation for obstructed lights, as we fear that in the future their confrères will not fare so well.

NOTES ON THE RE-DECORATION OF PREMISES.

Just now, during the very worst bit of slack season the professional experiences, he will do well to look round and furnish up his premises. Only too often does he make "press of business" an excuse for excess of litter, rubbishy specimens, and dilapidated rooms, but this excuse is of no avail at this season. To begin at the specimens most seen, show cases should receive attention, and any prints damaged by wet should be removed, instead of being left month in and month out, to the general lowering in tone of the display. In towns where many view these specimens daily, a constant change of photographs should be kept up, for remember that you not only wish to attract intending sitters, but also wish to create a desire to be photographed in as many other folks as possible. Any event of local interest, if photographically recorded, makes a good draw. Those cases which are distant from one's premises should receive constant inspection just now, for the fog and sticky atmosphere soon take the polish off the glass. The shop window, if you possess one, is subject to much the same remarks as the cases. Only too often does the photographer keep up a good display when trade is brisk, but gets slovenly when a slack time arrives. If anything, this should be vice versa, for to attract business is the thing.

The Receptionist in the Colour Scheme.

The porch with its display cases must, of course, be kept well swept and clean. If you are having the place redecorated use self-coloured wall papers, with perhaps a frieze; the case itself should be quiet and subdued, the better to show off its contents. The newer decorators and designers are supplying most artistic doors. One in leaded glass and fumed oak would probably create a favourable first impression. The walls of the shop or reception-room must be so treated as to be absolutely unobtrusive, and so as to show pictures to

the best advantage. The newer ways of treating walls with panelling, etc., give an artistic air to the place, but much can be done at small expense by use of a frieze and picture rail. The wall paper may be of any plain dark colour—say dark green, dark brown, or dark blue. We recently looked round a prominent provincial's reception-room treated in this latter colour. The walls were covered with the dark blue paper and the floor with a carpet of mixed blues and greens, the darker green predominating. There was a dark green picture rail and a plain white frieze above, with a stencil peacock with fan-shaped tail at intervals of about a yard. The chairs and tables were of old English oak. We were much pleased at the quiet yet perfectly satisfying effect of the whole; but judge of our surprise when the receptionist came, and we saw how perfectly she filled the setting. The lady's eyes were deep violet-blue, and she wore a blue dress. Certain it is that such small details make for the perfection of the whole.

Harmony in Colours.

If you cannot afford to have the assistance of a skilled decorator, remember, as in mounting, to go for harmony, and cut out as many colours as possible. If you wish to have more than one colour, use variations of shades rather than another tint.

A good carpet has a wonderfully refining effect. Let it be quiet in appearance, but also let it feel good to the tread. If you cannot afford really good old furniture, a set of chairs in the newer style of applied art will do excellently. Have nothing tawdry or gaudily upholstered.

The Dressing Room.

The same remarks as to furniture and carpets apply equally to the dressing-room, which, since it is used chiefly by the

fair sex, should have the appearance of a boudoir; therefore the furniture must be lighter and daintier. Since exhibition of pictures is not the chief requirement here, a light wall covering is to be recommended. One or two pictures on each wall of the best you produce will be quite sufficient. You will of course provide dressing tables and full toilet requisites. Do not be stingy with the latter. The brushes need not be silver mounted, but the difference between poor and good bristles is most marked. Do not forget the powder and a stick or two of black for the eyebrows. If cost is a consideration, the floor of this room may be covered with linoleum, with a large thick rug in the middle.

An Arrangement in Cream and Red.

If we may be allowed to give an example of general treatment, we will describe one dressing-room of a large establishment in the North. The proprietor explained as a start that he had a theory that rooms facing south and west, which caught the sun, should be treated with the cold colours—greens, blues, white, etc.—whilst those facing north and east should be finished in warm tones—reds, pinks, yellows, etc. This being so, and the room facing north, he wanted to use the warm tones, but also to keep the scheme light. Reds for this were impossible, though his carpet and fireplace, as well as mahogany furniture, were of this colour. He therefore decided to have cream walls, and if any of you have tried it you will know that this is the only colour to go well with rich deep red. The walls are done in a deep cream paper, plain but for faint perpendicular lines and bands of similar tone, giving height to the room. The picture rail, with all woodwork, is deep cream, whilst the ceiling is cream, and, separating it from the paper, the plain frieze is done in lemon yellow. The whole, with half a dozen suitable water colours on the walls (no photographs), is charming, the deep red carpet giving the necessary warmth.

Studio Matters—Walls and Floor.

Coming to the studio, it is difficult to treat of it, very few lending themselves to decorative handling. The same idea as to making draperies, carpets, and woodwork harmonise should be carried out here, having great regard, of course, for the work to be done under the skylight. Perhaps, again, we cannot do better than give a short description of another large studio, either for imitation or inspiration. Green is used as the predominating colour, chiefly on account of its non-actinic properties, for the modern photographer requires no reflected light other than that over which he has control. The walls are light green, whilst that part of the roof not covered with glass is a very dark shade of the same colour. The doors are dark green picked out with the lighter green. The glass sashes are also light green. The walls, where the background stands, are papered, the one in light green with skirting board the same, whilst the other is in dark green. There is a picture rail and frieze on each. These walls make a splendid background either for single figures or groups. Another cute arrangement that struck us was that for a distance of 8 ft. from each end the floor was covered with dark green cork carpet. This is a perfectly plain material, and makes a splendid ground for full-length figures, interior or exterior. This leaves about 20 ft. between the two ends uncovered. A plain patterned green linoleum is used for this, since the camera runs so much better on it than on carpet. The cork carpet was not used, since it is apt to show scratches, and it would be rather monotonous. You may think that mere dark and light green would have the same effect, but that is not so, for the camera and accessories supply plenty of other notes of colour.

Perhaps exterior painting is rather outside our province, but we cannot help reminding the reader that the skylight should receive a coat of good paint at least once a year, if leakage is to be guarded against.

W. FOSTER BRIGHAM.

ENLARGEMENTS IN SEMI-TINT.

THERE is nowadays a great demand for coloured pictures, as is witnessed by the many chromo-lithographs which flood various magazines, and yet photographers generally have been slow to appreciate the public taste in catering for it. The carriages of our various railway companies are adorned with coloured photographs effectively, and these to the ordinary travellers are much more attractive than the more sombre platinotypes, and albums, which they have displaced. Undoubtedly many of these are coloured too vividly, and we can imagine the disappointment of the pleasure seeker who visits Brightmud-on-Sea in squally weather, guided thither by a sunny-south-looking photograph of the place exhibited in the city train of the railway company interested in the place.

Enlargements in Colours.

But there are two sorts of coloured photographs, and I think if professional men directed their attention to the more sombre variety in connection with their enlargements, an increased revenue would result therefrom. Of course, to colour delicately an enlargement is a matter of time and skill, so that the price of the finished production is too great for the ordinary purse. But there is a method of colouring not commonly known, which to the initiated passes under the name of "semi-tint," and to the ordinary black and white artist the process is simplicity and speed.

Materials Needed.

Assuming that the reader has read a previous article on the "Rapid Retouching of Bromide Enlargements" in THE BRITISH JOURNAL OF PHOTOGRAPHY for January 13, let us imagine he

is about to work up an enlargement in semi-tint. Having provided a set of best quality water colours (cheap colours are unsuitable), the flesh, background, hair, draperies, accessories, etc., are washed over with the respective tints of colour necessary for correct rendering. This, at first, is perhaps easier said than done, as it is not always easy for a tyro to select either suitable colours or to wash over evenly, and although neither of these points is so imperative as when the picture has to be finished entirely in colour, yet both are in a way quite essential.

Speaking generally, the following colours will form a suitable selection, viz.:—Reds: Madder carmine, burnt carmine, pink madder. Browns: Vandyke brown, bistre, madder brown, brown pink, sepia. Yellows: Aureolin, yellow madder, or gall-stone. Blues: French ultramarine, cobalt, Payne's grey. Greens: Sap green, olive green. I have excluded some beautiful colours from the above list on account of their fugitive nature (most of the above are fairly permanent), and also others which have not a transparent nature. Opaque colours are undesirable.

How to Colour.

Now as to the method of procedure. First work out any blemishes in the enlargement and clean up the grain and retouching with lead pencil. Speaking personally, my next step would be to colour the background, and if it is vignettied, some harmonious tint, such as sap or olive green, cobalt or bistre, would be washed over with a large (No. 8) sable brush. In doing this the top of the enlargement might be slightly

raised from the horizontal position, but in making the other washes it should be level, to prevent the colours running downwards, and so giving a deeper tint at their lower extremities. Next the hair, draperies, and accessories should be tinted, and finally the flesh. If this is tinted first, it is most difficult to judge the correct depth of colour. Bistre is a most useful colour for brown hair, and very weak washes of the same, with perhaps a faint dash of aureolin or yellow madder, for the fairer shades, or stronger washes mixed with Payne's grey or Vandyke for darker brown. Pink madder will form a useful wash for clear, fair skin, or mixed with burnt carmine, madder brown, brown pink, or yellow madder, for other shades. The tinting must be done more heavily than if the picture is to be finished completely by colours. The cheeks, lips, eyes, jewels, etc., should be coloured sufficiently, but no attempt is to be made in shading.

Semi-tint versus Oil Enlargements.

Having tinted all parts needing colour, the enlargement is then finished (when perfectly dry and placed upon an easel) in black pastel, similar to the method described in the article previously referred to, only that it will not need so much work, and also that the wholesale tinting is not required.

The finished result should be very effective, and much superior to cheap oil enlargements, especially as the likeness is quite easily retained, whereas in the latter it is generally lost. And in reality the enlargement appears to be effectively coloured, as in ordinary colouring much of the shadow work is done in neutral tones, and this is well represented by the more rapid and velvety finishing in pastel. Of course, it must be borne in mind that the stump work materially subdues the tone of the colours, and this advantageously, as it allows of a bolder and more rapid treatment.

ARTHUR WHITING.

A NEW LIGHT FOR PHOTOGRAPHY.

I.

It is a singular circumstance that whilst process workers have almost wholly abandoned any dependence on daylight for their exposures, the portrait photographer still clings to the faith that there is nothing like daylight for his work. Thus he lies dormant for practically six months in the year, and in many cases almost starves. He has led the public to believe that portraits can only be taken in good daylight, and the public, taking him at his word, only go to him when the sun shines. A few of the more enterprising in the profession have, certainly, installed various forms of artificial light, but it has always seemed to me that they handle it half-heartedly, looking upon it merely as a makeshift, and using it only when there is no alternative but to do so or turn away prospective sitters. Some, no doubt, are using it as a means for getting up a little evening business, and a few in the metropolis and large provincial towns are using artificial lighting because of the impossibility of getting a skylight, or even a large slant side light. But under whatever circumstances electric or other artificial light is being used, so far as I can gather no one employing the same seems very happy with it.

Existing Methods of Artificial Lighting.

I have spoken of artificial lighting in the sense that there are other forms of it than the electric light—for instance, incandescent gas, acetylene, magnesium—but none of these latter means need be seriously considered, for I think it is generally admitted they are more of less of a nuisance. The umbrella arc lamp is perhaps the most generally used form of electric lighting for portraiture, but it is troublesome at the best of times to get even illumination and uniform exposures, a difference in the length of arc making considerable variation in the light. Then, again, it is expensive to run now that most of the public electric supply stations are serving current at 200 volts or over. This means that all voltage over about 45 has to be absorbed in resistance, and if the lamp is running with a current of 25 amperes, it is consuming five units per hour. As the price may be often as high as 6d. per unit, it is not pleasant for the consumer to know that his light is costing him 2s. 6d. per hour. The exposures may be short, but there is the time for focussing. If half a dozen plates are exposed on a sitter one may soon use up several units, especially when it is remembered that hand-fèred lamps draw more than their normal current when the arc is too short. Multiple carbon arcs have been introduced to deal with high voltages, each arc in series taking up forty-five volts, and a less current being taken, but the difficulty of equally regulating the arcs makes the advantage of such lamps doubtful. Incandescent electric lamps

in large clusters are even more expensive than arc lamps, and they are subject to the disadvantage that the bulbs gradually blacken with prolonged use.

Enclosed and Open Arc Lamps.

Enclosed arc lamps have been adopted to a certain extent, but whilst they consume less current and give a more actinic light than the open arc, their general illumination is uneven, and several lamps have to be used to get a sufficiently diffused light, so that the cost of current soon equals, and possibly exceeds, that of the open arc. For example, four enclosed arcs run in parallel on 200 volts, with a current of ten amperes each, will consume eight units per hour. The exposures may, however, be shorter than with the open arc, and all the lamps need not be put on at the time of focussing, so that perhaps there may be nothing to choose in the end between the open and enclosed arcs.

The Mercury Vapour Lamp.

However we look at the matter there would appear to be a distinct need for some form of lighting free from the disadvantages of the present systems, and cheaper to run. The Cooper-Hewitt mercury vapour lamp appears to fulfil this desideratum, and some notes upon it, drawn from actual experience of the writer in connection with an installation recently made by Penrose and Co., should prove interesting to the photographic fraternity.

The Hewitt light is not at the present time of any particular novelty, its peculiar features being pretty well known since 1903, when Mr. P. Cooper-Hewitt, of New York, first demonstrated his lamp in Europe. Moreover, Mr. Howard Farmer described one of these lamps at the Royal Photographic Society on May 12, 1903, and enlarged upon its advantages for photographic work. An experimental form of the lamp was then shown. Dr. von Recklinghausen also lectured on the lamp, and demonstrated it at the Camera Club on January 21, 1904. However, it did not come into regular photographic use in this country until last November, when the installation under notice was completed.

The Mercury Lamp in America.

In New York, however, the light had come much earlier into commercial use for photography. Pirie Macdonald, a well-known portrait photographer, so early as August, 1903, spoke in enthusiastic terms of the new light. He said: "For artistic portrait work it is all that I can desire; it is ideal. It is so soft that it does not affect the expression of the face, and yet so powerful actually that it is equal to daylight. I am enthusiastic about it, and believe that nothing which has been

discovered since the advent of the dry plate twenty-five years ago will so revolutionise photography, especially portrait photography, as will this light. It is an epoch-maker."

De Witt C. Wheeler, photographer and lantern-slide maker, of New York, writing on October 8, said: "I have now been using one of your Mercury lamps for about eight months for lantern-slide making, and am more than pleased with the results. A careful test resulted in the fact that, compared with the north light, the Hewitt lamp is three times as fast, and the quality of the slide is much finer both in grain and projecting quality. For photographic purposes of all kinds, from studio lighting down to photographic printing, it is a boon to the photographer, and no photographic workshop is complete without one."

Such positive opinions as these naturally aroused great attention, and the result is that the Hewitt light for photography is now quite common in the States. That it will soon be as commonly used in this country when once its advantages are realised, we do not doubt.

Some Historical Notes.

A few words on the history of the mercury vapour lamp will be interesting. In the first place, although it is commonly associated with the name of Mr. P. Cooper-Hewitt, the idea of producing light from incandescent mercury vapour is not his. So far back as 1860 the first experiments for the production of electric light by means of mercury electrodes was made, and there is a story that an English experimenter named Way lost his life from inhaling the mercury vapour whilst experimenting. It has, however, been shown that this is a fiction, that Way died from natural causes without acquiring much honour for his pioneer work. Rapieff in 1879 took out an English patent for a mercury vapour lamp, and in 1892 Aron followed, producing a workable mercury lamp which is in use on the Continent for scientific purposes, being regarded as an effective source of light for spectroscopic work and for optical measurements. The intense brightness of the line spectra of mercury and the separation of the lines over the

whole visible spectrum renders the lamp very adaptable for the calibrating of prisms, etc. It is said that the Aron lamp has several faults in the matter of convenience of handling, which prevent its coming into general use. Another form of mercury lamp is that of Dr. Gumlich, which is very similar to Aron's. Recently also an English-made lamp has been designed by Bastian, but chiefly with the idea of using it for street-lighting purposes. It is far too small and feeble for photographic work. An ingenious feature of it is a magnetic device for tilting the tube to start the lamp.

Patentable Features.

It will accordingly be gathered that there is no form of mercury lamp for photographic purposes that can be considered other than the Cooper-Hewitt, the patentable features of which consist, not in the actual principle of the mercury vapour lamp, but in the character of the lamp and its arrangements for working. Cooper-Hewitt must have the credit of teaching us how we can control the physical characteristics of the mercury vapour so as to enable lamps to be built which are practicable and commercially profitable.

An Incombustible Light-giving Element.

The mercury vapour lamp, as its name implies, derives its light from the gas or vapour of mercury, in which the passage of an electric current causes a high state of incandescence. In this respect it will be seen that it differs from all other forms of artificial light now in practical use, because they are usually dependent on the incandescence of a solid—usually carbon, either in the form of a filament or a rod, as in the ordinary glow lamp or arc, or in a finely-divided state as in gas and in paraffin lamps. In all such illuminants, moreover, there is a consumption of the light-giving element, but in the mercury lamp the vapour being enclosed in a vacuum, no consumption takes place, and no trimming is required.

In my next article I shall speak of the construction and working of the lamp.

WILLIAM GAMBLE.

THE WEEK IN HISTORY.

Pictorial Photography at the R.P.S. in 1853.

On February 3, exactly fifty-two years ago, the first ordinary meeting of "The Photographic Society" was held at the Society of Arts. If anybody at Russell Square is searching for precedents to justify the Society's active interest in pictorial photography, they need not look further than the report of this meeting in the first number of the "Journal of the Photographic Society." A paper was read by Sir Wm. J. Newton, "Upon Photography in an Artistic View, and in its relations to the Arts." Probably the audience who listened to it did not perceive in it the germs of endless controversies. Sir William sought to establish "that photography can only be considered as a science to those who investigate its properties, but that to the Public, its results, as depicting natural objects, ought to be in accordance (as far as is possible) with the acknowledged principles of Fine Art." A study of this paper will show how old is the artist's protest against photographic truth—as old as the photographer's against those methods of the artist which he holds to be illegitimate.

The Second Step in the Carbon Process.

Every carbon printer has cause to celebrate the third of February, though it is not the anniversary of any basic discovery in pigment printing. But that day in 1869 marks the point at which carbon stepped out from the leading strings of the adepts and became a process which anybody might take up. The date is that of the patent of J. R. Johnson, then director of the Autotype Company, wherein it was shown that

a rigid surface used as a temporary or final support needs no cement to fix the exposed tissue to it, "all that is necessary," says the patent, "being the perfect exclusion of air between the moistened surface of the tissue impressed by light and the impermeable surface to receive the picture as its support. . . . To effect perfect and permanent adhesion, the surface of the glass or metal forming the support must be chemically clean, particularly when such surface is polished. To avoid the necessity of thus cleaning the surface, I occasionally cover the surface with a very thin layer of plain collodion, using for this purpose a collodion containing one or two grains of cotton to the ounce of ether and alcohol forming the solvent. When the collodion is set, but not dry, I plunge it into water to wash off the solvents until the greasy appearance has ceased. I then lay upon the plate thus prepared the wetted tissue; when the picture is completed it adheres to the glass with great tenacity by surface adhesion only."

If the rigid surface was to be the temporary support of the tissue, which was to be re-transferred to paper, the glass or opal was coated with a fatty or resinous body of melting point above the temperature of the water used for development. It could then be transferred, correct as regards right and left, by applying a piece of transfer paper to the wet picture, or leaving the whole to dry. The image then separates spontaneously from the prepared plate in adherence with its final paper support.

I might mention here that Johnson introduced a flexible temporary support based upon his invention. He coated plain paper with an aqueous solution of shellac—ammonia, if I remember rightly—being the alkali used to get it into solution. The surface of the lac coating was waxed in the same way as the metal plates, and then used in a similar manner. The paper was known at the time as lac paper.

It was only one further step from the process of that date to carbon as worked at present, and that was taken five years later, when Mr. J. R. Sawyer introduced the "flexible temporary support."

The Calotype Process.

It will be shown in a later issue of these notes at what point Fox Talbot introduced the development of a latent image into his methods. As pointed out by the Editors last week, he did so subsequent to Daguerre's process becoming known. I share the view that there is nothing in any of Talbot's writings ante-dating Daguerreotype, to show that the conception of a latent and developable image originated with him. The first heard of that was the patent of his "Calotype" process, which he took out on February 8, 1841. Calotype, to describe it briefly, consisted in treating paper first with silver nitrate and then, after drying, with potassium iodide. This iodised paper could be kept indefinitely, but it was scarcely sensitive to light. Talbot imparted sensitiveness to it at the time of use by the mixture of silver nitrate, gallic and acetic acids, which he called "gallo-nitrate of silver." This "Calotype" paper was exposed, dry or moist, within an hour or two of its preparation, and an image obtained which might be faintly discernible or quite invisible. In either case, it was brought to full strength with the gallo-nitrate of silver. As fixing agent Talbot used potassium bromide, by which the excess of silver in the paper was removed. It might be thought that such a process would not give permanent results, but Mr. C. H. Talbot still has in his possession a number of negatives made in this way during the forties. Until the use of hyposulphite of soda became clearly understood, bromide or chloride as a fixing agent was preferred by Talbot and other early workers.

Talbot's Patent Claims.

In this patent (No. 8,842, 1841) Talbot claimed a number of things, viz:—

The use of gallic acid, or tincture of galls, in conjunction with silver nitrate, to render iodised papers more sensitive.

Development, or, as he describes it, "the making visible photographic images upon paper, and the strengthening such images when already faintly or imperfectly visible by washing them with liquids which act upon those parts of the paper which have been previously acted upon by light."

Obtaining portraits from the life by photographic means on paper.

Fixing with potassium bromide or other soluble bromide.

Printing from photogenic pictures on to a different kind of sensitive paper.

In 1854 Talbot took action (Talbot v. Laroche) in support of this patent, which he alleged was infringed by workers of the collodion process, then newly introduced by Scott-Archer. The chief ground for action was that a sensitive collodion film developed with pyrogallic acid was an infringement of his sensitised iodide paper developed with gallo-nitrate of silver. But verdict was given for the defendant on the finding of non-infringement. The case is the most notable of any in the annals of photography, for it liberated inventors from the trammels with which they were threatened in Fox Talbot's patent. The Calotype process was almost immediately superseded by wet collodion.

Fox Talbot's Sun Prints of 1835-6.

As bearing on Fox Talbot's process of fixation with bromide and other haloid salts, it may be interesting to note that Mr. C. H. Talbot has in his possession a print fixed in this way which is sixty-five years old, for, according to the note on it in Fox Talbot's handwriting, it was made by him on February 6, 1836. It is a copy by contact of a fern print, and was probably fixed with common salt. A still earlier example, a negative made in the camera in 1835, also exists, and though it is probable that neither are in the same state as when first made, their present condition is a proof of the efficacy of this method of fixing.

HISTORICUS.

PHOTOGRAPHING THE INTERIOR OF THE EYE.

A Paper in "The American Inventor."

To get behind the curtain of the living eye, to put an X-ray, as it were, upon the diseases back of that impenetrable barrier, has been the aim of every scientific oculist for over a century.

In a long series of experiments with photographic apparatus I have been successful in designing a camera which is partially successful in photographing the delicate interior structure of the human eye.

In photographing behind the hitherto impassable curtain to secure a picture of the net-skin, or the skin over which extends the interlaced network of nerves of the background of the eye, there are a number of difficulties to be overcome before success can be achieved. It is necessary while taking such a photograph that the patient obtain a perfectly restful position of the eye, without which a photograph is of no use, for it will not show a correct condition of sight, muscle or nerve. Movement of the eye during the photographing so blurs the picture that it is impossible to ascertain the nature of the disease.

The Difficulty of Long Exposure.

Now, in all past attempts the photographic apparatus used necessitated an exposure of some minutes' duration with a strong outer light, and no patient could hold the eyes perfectly still in a normal position for the necessary length of time without the result being a

strain which would develop momentary trouble not natural to the subject. Few persons possess the physical control over the muscles of the eye to keep perfectly quiet during the time required for photographing by this method. Later there was an apparatus brought forth in which vivid flashlight powder was used in order to make the picture instantaneous, but the shield for the eye could not be made strong enough in this instance, and the machine was a failure.

I knew that could the camera be invented which would overcome these two obstacles many now totally blind persons could be made to see. Very frequently a physician is obliged to pronounce the sight of a patient entirely gone because of the fact that he cannot examine the background of the eye.

A Cat's Eye.

My experiments in developing a camera adapted for viewing the eye's interior met with many failures, and an occasional partial success. In the early attempts at eye-photography I found that a cat was the most satisfactory subject, because the eye of the cat throws out from fifty to one hundred times more light than does that of a human being, even when in normal condition. In a cat's eyes there is a particularly strong light, perfectly shielded back of the net skin, which enables the animal to distinguish in a dim light objects which would be unseen by the human eye. In the cat family, the

rays of light are thrown back, and pass a second time through the net-skin. This condition was a great aid in my experiments. I knew that the device which would successfully photograph the interior of a cat's eye would lack many degrees of power necessary to achieve the same result with the human eye.

Placing the Patient

The invention which I designed for this work is arranged with a light, but strong, chin-rest attached to the right-hand side of the camera. This enables me to obtain the necessary restful pose of the head without any effort or undue strain on the part of the patient. Opposite where the eyes are focussed when resting at normal or when the patient is looking straight in front in an easy position, is placed an adjustable eye-glass or lens. This has a special finder placed sideways to bring to a correct focus the eyes of the subject without obliging him to move his chin from the rest or making it necessary for him to shift his eyes from front, in which position a more complete photograph can be secured. A petroleum lamp fixed back of the adjustable lens makes it possible to light up the background of the eye by rays that are neither too strong nor irritating for even a badly-diseased eye. The photographic camera is attached to the observation tube or eye-glass lens. This consists of a short tube which is attached to the bulb which regulates the shutter of the camera. Attached to the back of the camera is a tin-covered slide which protects the operator and also the patient being examined from the dust of the flash powder.

All my early experiments were made on animals, for their eyes are much stronger than a person's, and I could try various combinations without fear of sending the subject blind. Not until I knew that I had at last evolved a perfect apparatus did I photograph the background of a man's eye.

Illumination by Flashlight.

The method of securing these valuable interior photographs is simple in itself once the manner of operating the apparatus is comprehended. The pupils of the patient are enlarged by the injection of "drops." He then places his chin on the rest and the lamp is swung into position and lighted. It is then possible to see in the special

eye-finder and in the glass slide at the back of the camera a good, sharp picture of the eye. The special focus, or searcher, is turned and regulated until the eye is brought in exactly the right position for a properly focussed picture taken with an ordinary camera. This accomplished (it takes but a few moments to make these arrangements) the subject can remove his chin from the rest and retire to some other part of the room, if he so desires. While he is resting the especially prepared plate, or negative, is put in the camera, the flash powder prepared, and everything put in readiness for the squeezing of the bulb and the taking of the picture.

Exposure.

The patient then returns and places his chin in the rest, the indicator marking the identical spot he had it in when the first focus was obtained, and the position of the eye is also indicated, so that there need be no second focussing. Now comes the simultaneous discharge of the flash powder and the opening and closing of the shutter, which completes the operation. The photograph is secured inside of fifteen minutes after the camera is brought out, and nearly all this time is used in setting up the apparatus. In getting the proper flash powder it was necessary to make a number of experiments before securing the kind which would do the work without hurting the eye even momentarily. I also had to construct a special machine for exploding the powder, so that the jar should be done away with and the most powerful light attained. Great care must also be taken in selecting photographic plates, for the background of the human eye presents an appearance of red on red, which is a particularly trying combination. red in itself being a colour unfavourable for photographic purposes. At last, after careful search, I found a satisfactory make of plates, and my prints came out clear and sharp.

A perfect picture of the interior of the eye does not consist of but one photograph, but of a series, the specially desired part of the eye being brought right in the centre of the composite picture if desired.

The invention is as yet too new for all its possibilities to be realised; but much relief can now be given to those suffering from optical troubles which have always been pronounced incurable.

DR. WALTER THORNER.

NEW EXPEDITIONS FOR THE OBSERVATION OF THE TOTAL SOLAR ECLIPSE OF AUGUST 30, 1905.

THE great astronomical event of the present year (1905) will doubtless be the total solar eclipse of the sun, August 30. Plans are now being formed, writes the "Scientific American," with regard to eclipse expeditions, the choice of observing stations being specially favourable. Several well-equipped expeditions will probably be sent from this country and Europe.

Mr. William H. Crocker, of California, has generously offered to defray the expenses of expeditions to be sent from the Lick Observatory to Labrador, Spain, and Egypt, and the provisional programme for the three stations is, in the main, as follows:

In Labrador, a photographic search will be made for intramercurial planets, in a region of the sky $8\frac{1}{2}$ deg. wide, extending in the direction of the solar equator from 4 deg. below the sun to 15 deg. above it. It has been thought likely that there may be one or more planets between the orbit of Mercury and the sun, and during a total eclipse they would become visible, if ever. On the whole, however, the observations so far made negative the existence of any body of considerable size in this region, though in 1878 Prof. Watson and Mr. Swift, it was thought, had discovered one, if not two, such planets.

Observation Centres.

In an article contributed by Prof. W. W. Campbell, of the Lick Observatory, to the "Popular Science Monthly," for June, 1904, he

writes: "The eclipse of August 30, 1905, will occur when the earth is seven degrees from the plane of the solar equator. It will therefore be advisable to search over a region of considerably greater width than was the case in 1901. Inasmuch as increased area means increased instrumental equipment, expense, and difficulty, a corresponding shortening of strip to be observed would perhaps be justified. It is to be hoped that observing parties well equipped for the intramercurial search will be located in Labrador, Spain, Tunis, and Egypt. If clear weather prevails at any of the four stations, very valuable results may be secured. Should a new planet be observed at three such stations, the enormous interest attaching to its discovery would be heightened by the fact that its approximate orbit could be determined at once. If no planets are revealed on first-class plates, the negative result would be scarcely less valuable, though certainly less interesting, than positive results; and the intramercurial question would cease to be a pressing eclipse problem."

The Photographic Equipment.

Owing to the generosity of Mr. Crocker, a photographic search for intramercurial planets will be made not only in Labrador, but in Spain and Egypt as well. In Spain the photographic intramercurial search will cover a region of $9\frac{1}{2}$ deg. wide, extending in the direction of the solar equator from 14 deg. below to 14 deg. above the sun. In Egypt the photographic intramercurial search will cover a region

of $8\frac{1}{2}$ deg., extending in the direction of the solar equator from 4 deg. below to 15 deg. above the sun.

Photographs of the corona by means of a camera of five inches aperture and forty feet focus, of the form first used by Prof. Schaeberle at the eclipse of 1893, will be made at Labrador, Spain, and Egypt. The large-scale coronal photographs made by Schaeberle at that eclipse opened a promising way for determining an explanation of the changing form of the corona, and whether the coronal streamers are moving in or out, or both, or neither, a question that has not yet been satisfactorily answered. Photographs of the corona should be secured for this purpose at widely separated stations, and the circumstances of the widely separated stations in Labrador, Tunis, Spain, and Egypt seem admirably adapted for solving this most important problem at the coming eclipse.

In Spain, a study will be made of the polarised light in the corona. These observations with the polariscope are for the purpose of determining the relation between the reflected and intrinsic light, and perhaps the size of the reflecting particles which are distributed through the corona.

Photo-Spectrographic Records.

The expedition in Spain will also be provided with spectrographs with moving plate-holders, which will be used to obtain a continuous record of changes in the spectrum of the sun's edge at the time of second and third contacts; and other spectrographs for determining the wave-length of the green coronal bright line, and, if possible,

the wave-lengths of the bright and dark lines in the isolated spectrum of the sun's edge, as nearly as possible at the time when the dark lines give way to the bright ones, and vice versa, and of a spectrograph for recording the general spectrum of the corona.

This is merely an outline of the programmes for the three eclipse expeditions to be sent from the Lick Observatory, California, to Labrador, Spain, and Egypt respectively. The details of the programmes have not yet been fully worked out, but will be announced later.

The Yerkes Observatory will not send any expedition to observe the total eclipse next August, but the Naval Observatory, Washington, D.C., will probably send three expeditions, one of which may be located near Burgos, in Spain.

Prof. E. C. Pickering, of the Harvard College Observatory, Cambridge, Mass., states that there will be no official expedition from the observatory. However, Mr. L. W. Ripley, of Hartford, Conn., intends to conduct a party under the auspices of a local amateur scientific society.

An expedition composed largely of amateurs will go to Burgos, Spain, which is probably one of the most desirable stations along the route of anticipated darkness. A programme is being arranged for covering the minor details of an eclipse, such as observations of the diminishing sunlight and the peculiar shadows cast by the foliage on the ground when the sun is nearly eclipsed.

MARY PROCTOR.

FOREIGN NOTES AND NEWS.

Testing Collodion for Collodion-Chloride Emulsions.

HERR WANDROWSKY gives in the "Photographische Mitteilungen" the following method of testing collodion for making printing-out collodion emulsion. It should be free from alkali, as shown by addition of a few drops of a 1 per cent. solution of phenolphthaline; if it becomes reddish violet, even if only faintly, hydrochloric acid should be added drop by drop till this reaction no longer occurs, and the collodion remains colourless. If the proportion of alkali is very great the collodion should be rejected, as it would otherwise give a coarse granular silver chloride. The collodion should be free from sulphates. These may be tested for by the addition of a small quantity of barium chloride—if a white precipitate is formed the collodion should be rejected. In making a collodion, care should be taken to filter the alcoholic solution of citric acid immediately before using it, as the little fibres may cause the separation of silver citrate. Careless addition of glycerine may also cause precipitation of the emulsion, and therefore it should always be diluted with three times its volume of alcohol, and added in a fine stream and with constant shaking

Under-exposure.

In Liesegang's Almanac for this year, Dr. Georg Hauberisser, of Munich, states that he has found that by the use of an edinol developer, followed by uranium intensification, he can compensate for an eight times under exposure as compared with hydroquinone. His method of experimenting was to use a stereo camera with identical lenses, the one stopped down to $f/11$, the other to $f/31$, the plate was then cut in two, and one half developed to full density with hydroquinone, and the other developed with edinol, and subsequently intensified with the uranium intensifier. Comparative half-tone illustrations are given, but one may reasonably doubt the practical value of such experiments, and question whether precisely the same results could not have been obtained by only developing for a short time with hydroquinone and then using the uranium intensifier.

A Bathing Formula for Panchromatic Plates.

Professor Valenta, in the above-named almanac, gives his latest formula for the making of a panchromatic plate, with the aid of ethyl violet, which he first suggested for use with collodion emulsion. His first trials to sensitise gelatine plates with this dye were a failure, because he used too strong a bath; the tinctorial properties of ethyl violet, like all the other aniline violets, being very great. Finally, he found that bathing a dry plate with a 1:250,000 solution with a little ammonia for three or four minutes gave a strong band of sensitiveness extending from C to D, with a fainter band extending from D to E. This obviously gives a minimum about E, and to fill this up he now suggests the use of monobromofluoresceine; and erythrosine to strengthen the yellow-green. He prepares a stock solution of:

Ethyl violet solution (1:5,000)	100 parts.
Erythrosine solution (1:500)	20 parts.
Monobromofluoresceine solution (1:500)	30 parts.

Fifteen parts of this are diluted with 500 parts of water and 2 parts of ammonia added. The plates should be bathed in the dark in this for three minutes, and then washed in a similar solution strongly diluted and dried at a moderate heat.

A New Developer.

Rudol is the name of a new developer which has just been introduced on the Continent, and for which some extraordinary claims are made. In the first place, it is not a developer of the ordinary kind; by its use very much under-exposed negatives show more details in the shadows than with all other developers, and this it is stated to be due to the fact that besides the ordinary process of chemical development there is also a physical development, and the excess of silver remaining in the film is used up to intensify the image produced by chemical development. Over-exposure is also compensated for without any alteration of the developer, halation is done away, and a negative exposed on a subject with very great contrasts, as, for instance, the interior of a room, including a brightly-lit scene in-

cluded by a window, shows details in the high lights and details in the shadows. It is sent out as a concentrated solution, which must be diluted with five times its volume of water, 0.02 per cent. carbonate of potash, or 0.06 per cent. of carbonate of soda added. The duration of development is stated to be from three to ten minutes, according to the exposure; 0.006 per cent. of potassium iodide is stated to be a powerful restrainer. The concentrated solution is said to keep indefinitely.

Solubility of Developing Agents.

M. Gravier has determined the solubility of the principal developers in water and in solution of sodium sulphite, with the following results:—

Developing agent.	Solubility in 100 parts of water.		Solubility in 100 parts of 10 p.c. solution of sodium sulphite at 15° C.
	15° C.	45° C.	
Adurol	100	more than 100	65
Amidol	30	33	28
Eikonogen	7.8	17	4
Glycine	0	0.2	Traces.
Hydroquinone	6	14	4
Metol	5	9	2
Ortol	36	52	0.75
Paramidophenol Hydrochlorate	7.4	11	0.8
Pyrogallol	59	more than 100	59

Cobalt and Lead Toning of Bromides.

MM. Lumière and Seyewetz have suggested the following as a method of obtaining green tones on bromide and other development papers. The prints must be very much over-developed, as they lose considerably in toning, and they must be thoroughly freed from all traces of developer or fixing solutions. Bleach the print in:—

Ferricyanide of potassium	60 g.
Lead nitrate	40 g.
Water	1,000 ccs.

Then wash thoroughly and immerse in

Cobalt chloride	100 g.
Hydrochloric acid	300 ccs.
Water	1,000 ccs.

for one or two minutes, when it will at once assume a brilliant green tone. A thorough washing afterwards is essential.

Cyclopædism at Work.

In 1902 the "Revue Belge de Photographie" appealed to its readers for aid in forming a bureau for photographic information, for prints and negatives, photographic books and journals, and the collection thus formed was placed at the disposal of subscribers; now, however, it has grown so much that it has moved to central and more commodious premises, Rue du Musée, Brussels, and has blossomed out into the Institut International de Photographie. Its principal object is the popularisation of photography, and the Institut has, with this object in view, collected and classified everything concerning the theory, practice, and art of photography. It is divided into two sections, the first comprising (a) a collection of trade catalogues, rules of societies, exhibition rules, and notices of the latest trade novelties; (b) bibliographic section, a collection of all French books and periodicals, lists of works, and articles on every subject; (c) tourists' information, list of dark-rooms and dealers, details of tours, choice of routes, what to photograph in every district (100,000 examples can be seen); (d) a permanent exhibition of the most beautiful specimens produced by the leading firms of the world; (e) a collection of all photographic magazines and journals of the world, facilitating the choice of subscription; (f) information and

advice as to the purchase of apparatus, accessories, works, etc. The second section is, we gather, extremely important, and may be summed up as the archives, and great stress is laid on the fact that by its aid one can ascertain the various schools in photography, follow up their evolution and that of each "master" in pictorial photography, the works of every painter, the effects of light and shade in the works of Rembrandt, the discovery of Gainsborough in posing the hands, etc., etc. The only thing wanting to make it perfect is a button that can be pressed, and which will enable the visitor to obtain anything and everything without search or trouble.

Sensitive Silver Compounds.

Dr. Gunther recently described before the Society of Natural Philosophy at Basle his experiments on the so-called photo-haloids of silver, and had made these of different compositions by mixing a solution of colloidal silver with estimated quantities of chlorine and bromine water; precipitates were obtained which the author considers as solid solutions of silver in the silver haloids, and not as solutions of the sub-haloids in colloidal silver. Some of them are very colour-sensitive, and good spectra have been obtained on them, but they are of no practical importance, as the images are very weak.

Photo-Mechanical Notes.

The Angle of Three Colour Screens.

Some people have an idea that where two cross line screens are used in three-colour work to avoid pattern, one make of screen may give less objectionable pattern than another. Whether this arises from the soft insinuations of those desiring to dispose of screens, or from the prejudice of those using a particular make, we are unable to say, but certainly, after having used the screens of Max Levy, Haas, and Johnson for three-colour work, the pattern formed does not seem to be in any case more or less obvious than in the others.

To obtain the minimum of pattern in three-colour, it is necessary that the lines should meet each other to make the widest possible angle at crossing. Now, there are six lines in any three-colour print (two for each colour), so that if we take the diameter of a circle as our base line and draw six lines from its centre, it will be found that they are spaced at the greatest possible distance from each other when the angle of each line is 30 degrees from the one next to it. If, therefore, for one colour, the normal screen is taken, one of its lines will give an angle of 45 degrees to the right, and the other 45 degrees to the left, or counting round, 45 degrees and 135 degrees. The second screen must, therefore, have lines ruled so that each component is 30 degrees away from the lines of the normal 45 degree screen, as, for example, one component at 15 degrees from the base and the other at 75 degrees, so that turned round they will read 105 degrees and 165 degrees. It will be found that we now have lines at 15, 45, 75, 105, 135, and 165 degrees, each of which is exactly 30 degrees from the preceding line. If any other angle but 45 degrees is taken for the normal screen with the cross lines at right angles to each other, then, of course, the colour screen would have to be at other angles than 75 degrees and 105 degrees, in order to get the 30 degrees to afford the minimum of pattern, but the final result cannot possibly be better than that obtained with screens ruled in the usual way.

The use of one large circular screen seems quite common on the Continent, the screen itself being turned to the different angles for the different colour negatives. Max Levy, who formerly advocated the pair of screens ruled as indicated above, in an article in the current "Process Year Book," modifies his previous opinion, and points out the advantages of the circular

screen, and he is making a fitting for it to be placed in the back of the camera, which will enable the screen to be turned to the correct angle with ease and exactitude.

Rotary Intaglio Processes.

Reviewing current reproduction processes in the "Jahrbuch des Photographen," Walter Ziegler comments on the rationale of the process which is well known in this country as the Rembrandt. It can be easily seen, he writes, that an exceedingly fine screen is used to get the grain. The printing portions of the plate being in intaglio, the fineness of screening which can thus be introduced is almost unlimited, as there is no danger of undercut. Printing on a suitable rapid press can be done in conjunction with inking by rollers: this latter becomes practicable on adjustment of the etching to the correct degree of shallowness and preparation of the non-printing portions to repel the ink.

All of which we would say is perfectly true, but is not much help to anybody who is struggling with the problem of commercial rotary intaglio printing. But Herr Ziegler's reticence may have something to do with his announcement that recent experiments in Germany in this branch of printing have met with good success.

Process Man and Artist

The same writer dwells on the importance of bringing together the creators of artistic works and their reproducers, and points out that this end is kept prominently in view by schools. The Munich School of Photography, he states, has specially set itself to this task, and has proved the good results which spring from such close association by a number of exhibitions. Too often the reproducer has no means whatever of learning anything of the aims and feelings of the artist, and if the photo etcher can be brought into sympathy with the painter and draughtsman there should be less need for artists' criticisms of reproductions of their work. Under present conditions, when so much of the work falls upon the etcher, such education of him is all the more desirable.

A Stable Albumen Solution.

The difficulty of keeping albumen solution is well known, and, whilst there are many preservatives, they are not capable of being used, as they would precipitate the albumen. However, Franz Novak, in the "Photographische Korrespondenz," states that he has kept for a month in a loosely-closed bottle a solution of dried albumen to which carbolic acid was added. The actual method of making it is as follows:—Two grammes of crystallised carbolic acid are mixed with 980 ccs. of water and 140 grammes of dried albumen added, the mixture well stirred, and allowed to stand for about three hours till the albumen has softened; it should then be rubbed up in a mortar till complete solution is effected and then filtered through cotton wool.

The Half-tone and Photography.

"The use of half-tones in advertisements is responsible for the enormous progress made in commercial photography during the last ten years, and all signs point to a continued elaboration and extension of this branch of industry. Whatever may be said of the relations or divergencies of art and photography, there can be no doubt that the commercial photograph is more effectively convincing than any amount of sketching and drawing. The catalogue, prospectus, price list, folder, or magazine advertisement which is now printed without a photographic illustration is the exception."—H. Bentley in the "Chicago Tribune."

A subject of importance to process workers and printers is fixed for Monday next, the 6th inst., at the Society of Chemical Industry, when a paper on "The Fading of Inks and Pigments" will be read

by Mr. J. W. Lovibond. The meeting is held at Burlington House, Piccadilly, London, W., at eight o'clock, and visitors are admitted on introduction by members, on application to the secretary of the society.

The exhibition of photo-engraving at South Kensington is still without a definite date for its opening, but we understand that an announcement will be made shortly. The exhibition is to be held in the Victoria and Albert Museum, South Kensington, and inquiries with reference to exhibits should be addressed to the Secretary, Exhibition of Process Engraving, Board of Education, South Kensington, London, S.W.

The International Photo-Engravers' Union of America have adopted "The Illustrator" as their official organ. In the current issue, President Louis Flader reports, among other matters, that the council has adopted a plan by which apprentices in small cities in which no union exists can be registered, thus enabling the Union to keep track of their term of apprenticeship. Under the new law, and with provisional membership laws in existence, there is no excuse for any man working at the photo-engraving trade anywhere in the country not being affiliated with the I.P.E.U.

Exhibitions.

WEST HARTLEPOOL AMATEUR PHOTOGRAPHIC SOCIETY.

THE second annual exhibition in connection with the West Hartlepool Amateur Photographic Society was opened on January 19 in the Victoria Hall. The pictures on exhibition numbered over 200, and included examples of the work of many of the most eminent exhibitors in the kingdom. Mr. T. Fitzgibbon Forde, of Sunderland, acted as judge, and his awards were as follows:—Silver medal for best picture in competitive sections: A Foster, Bishop Auckland, "The Hour When Daylight Dies." Open classes—Landscape—Bronze medals: H. Lincoe, Sunderland, "Old Durham," and A. Marshall, Nottingham, "Hauling Sail"; certificate, J. Turner, Sunderland, "In the Harbour." Architecture and portraiture—Bronze medals: Miss H. Stevenson, Birkenhead, "Her Eyes are with Her Heart, and that is Far Away," and A. Marshall, "The Rose"; certificate, W. A. Clark, Moseley, "An Old Cottage." Any subject not included in previous classes—Bronze medals: E. Seymour, Watford, "Flower Study," and A. W. Walburn, West Hartlepool, "Ivy Geranium"; certificate, Dr. F. Ward, Ipswich, "Aquilegia." Lantern slides—Bronze medals: Rev. H. W. Dick, Manchester, and H. Wornleighton, Leicester; certificate, W. Farren, Cambridge. Members' classes—Landscape—Bronze medals: J. J. Herbert, "Woodlands," and J. W. Walker, "Murky Tees"; certificate, J. T. Stanley, "When Trees are Bare." Any other subject—Bronze medals: A. Gibb, "Narcissus," and J. T. Stanley, "Rydal Water"; certificate, E. F. Jones, "An Old Fisherman." Hand camera class—Bronze medal: M. Willis, "Ebb of the Tide"; certificate, Geo. Welch, "Through the Wood."

BRIERLEY HILL CAMERA CLUB.

ON January 28 the tenth annual exhibition organised by the Brierley Hill and District Camera Club was opened in the Town Hall. The open section is numerically a little weaker than last year, but the quality quite reaches the average. In strength the members' exhibits are about the usual number, but there is a distinct improvement noticeable in the work. An attractive feature in the exhibition is the loan collection from the Birmingham Photographic Society. In the open section there are sixty-five entries and the awards of the judges (Messrs. W. R. Bland and J. Page Croft) are as follows:—Silver

medals, E. J. Jarvis (Plymouth), W. Clayden (Plymouth), C. F. Grindrod (Malvern); bronze medals, William Northwood (Brierley Hill), and A. W. Cooper (Preston); certificates, F. G. Tryhorn, Alfred Roffery, and E. Seymour. Members' Section: Silver medals, H. B. Cookson, Mrs. A. M. Wallington; bronze medals, Hugh Price, Herbert Whitford, William Northwood; certificates, Mrs. Walter Cochrane, J. C. Bunce, A. Gordon Smith. Lantern slides: Silver medal, J. Stabb; bronze medal, S. G. Kimber; certificates, William A. Clark and T. G. Tryhorn. Altogether there are nearly 280 exhibits.

FORTHCOMING EXHIBITIONS.

January 28-February 12.—Photographic Society of Marseilles. Secretary, M. Astier, 11, Rue de la Grand-Armée, à Marseille.

February 6-11.—Blairgowrie and District Photographic Association. Hon. Secretary, Wm. D. M. Falconer, James Street Cottage, Blairgowrie.

February 14-15.—Royal Albert Institute, Windsor. Hon. Secretary, Mr. Jas. W. Gooch, 9, High Street, Windsor.

February 15-March 15.—International Exhibition Artistic Photographs, Vienna. Hon. Secretary, Dr. Reiniger, Camera Club, Largerplatz No. 3, Vienna III., 3.

February 16-18.—Norwich and District Photographic Society. Hon. Secretary, E. Peake, Rydal House, Earlham Road, Norwich.

February 21-March 7.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

February 24-March 4.—Northampton Photographic Society. Entries close February 7; for pictures, February 17. Hon. Secretary, E. J. Felce, 83, Adam's Avenue, Northampton.

February 25-March 4.—Birmingham Photographic Society. Hon. Secretary, Lewis Lloyd, Norwich Union Chambers, Congress Street, Birmingham.

February 25-March 11.—Edinburgh Photographic Society. Entries close February 11; for pictures, February 15. Hon. Secretary, J. S. McCulloch, 3A, North Saint David Street, Edinburgh.

March 4-11.—South London Photographic Society. Hon. Secretary, H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 7-14.—Brentford Photographic Society. Hon. Secretary, F. H. Read, Ferndale, Clifden Road, Brentford.

March 16-30.—International Photographic Exhibition, Earl's Court. The Organising Managers, 119-125, Finsbury Pavement, London, E.C.

March 20-25.—The Cripplegate Photographic Society. Hon. Secretary, John B. Parnham.

March 27-April 1.—Leicester and Leicestershire Photographic Society. Entries close on March 20, 1905. Secretary, R. Warden Harvey, Oriental Cafe, Market Place, Leicester.

April.—International Exhibition, Genoa. Sec. Gen., Piazza Fontane Marose 18, Genoa.

April 3-15.—Photographic Society of Ireland. Hon. Secretary, R. Benson, 35, Molesworth Street, Dublin.

April 7-May 8.—International Artistic Exhibition, Berlin. Director, Herr Franz Goerke, Maassenstrasse 32, Berlin, W.

May 1-31.—International Exhibition of Photographic Picture Postcards, concurrently with the 10th Salon. M. le Secrétaire Général du Photo Club de Paris, 44, Rue des Mathurins, Paris.

May 10 to June 19.—Salon of the Photo Club de Paris. Entries close March 1, and pictures must arrive by April 10. Secretary, Paul Bourgeois, 44, Rue des Mathurins, Paris.

June.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

March 31.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Limited, Ilford, E.

September.—Kodak. £400 in prizes for results on Kodak products. Kodak, Ltd., 57-61, Clerkenwell Road, London, E.C.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents were made between January 15-21, 1905:—

FLASHLIGHT.—No. 828. "An improved photographic flashlight apparatus." Marwood Short, 21, Chapel Road, Anfield, Liverpool.

PENDANTS.—No. 1,042. "Improvements in and relating to lockets, photograph pendants, or the parts thereof." Thomas Wilcox, 111, Spencer Street, Birmingham.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

PORTABLE DARK ROOMS.—No. 5,586, 1904. "A portable photographic dark room comprising a framework adapted to be folded up and raised or extended at will, enclosed in a double thickness of black cloth, having apertures for the passage of the hands and a larger aperture for the introduction of the framework and the plates or apparatus, and capable of being hermetically closed, said cover being provided with two frames with red glasses substantially as described and shown." Annet Meunier, 10, Rue Victor Hugo, Lyons, France.

SENSITISED PLATES FOR COLOUR PHOTOGRAPHY.—No. 25,718, 1904. "The present invention relates to improvements on an invention for which application for British patent was made on October 25, 1904, No. 22,968" (see B.J. January 6, p. 10), "and has for its object to explain that the coating of coloured particles interposed between the sensitive coating and the glass which serves for its support is not necessarily formed of two superposed elementary coatings, as indicated in the specification of said former application for patent; and that, on the other hand, the result sought may be obtained, not only by the six colours—red, yellow, blue, orange, green, and violet—but also by any given number of colours, distributed as equally as possible over the entire coating, and covering as far as possible the entire surface without superposition." A. Lumière et ses Fils, Lyons-Monplaisir, France.

SELF-TONING PAPERS.—No. 26,247, 1904. "Protection is claimed in a self-toning printing-out paper, the use of a new vehicle or medium, consisting of a mixture of agar-agar and arrowroot, or other suitable starch, in lieu of gelatine or collodion, the vehicles or mediums now in common use. The paper or other suitable material is coated with a warm, sensitive emulsion made as follows:—To 24 ounces of water add 1½ ounces of arrowroot or other suitable starch and boil. Dissolve in this mixture when cool: Sugar, 6 drachms; citric acid, 5 drachms; ammonium chloride, 64 grains; Rochelle salt, 4 drachms; and mix thoroughly. Add slowly 9 drachms 36 grains of nitrate of silver dissolved in 8 ounces of water. Next add slowly 11 grains of chloride of gold dissolved in 6 ounces of water. Finally take agar-agar 2 drachms boiled till dissolved in 18 ounces of water, and add warm to above mixture. Dry the coated paper, or other suitable material, in a dark chamber. The sensitive paper or material may then be printed by exposure to light under a photographic negative in the usual manner until a visible image of sufficient strength is obtained. If a print of a purple-brown tone is required the printed paper, or other material, is first washed for about ten minutes in running water, and is then

fixed and toned in one operation by immersion for about fifteen minutes in a bath of hyposulphite of soda solution containing about 20 ounces of hyposulphite of soda to 100 ounces of water. If a deeper purple-toned print is required, before washing or using the hyposulphite of soda bath the print is immersed for 15 minutes in a bath containing chloride of sodium 20 ounces, water 100 ounces. The reason for using agar-agar and arrow-root or other suitable starch as a medium in which to carry the light-sensitive salts instead of the usual vehicles, which are gelatine or collodion, is because when gelatine is used the gold salt is not so easily reduced, and will not give such satisfactory tones by immersion in hyposulphite of soda solutions only, while collodion as a vehicle is more costly." E. C. Morgan, Kew Foot Road, Richmond.

ROLLER-BLIND SHUTTERS.—No. 5,522, 1904. "According to the description, an endless cord is passed round the two blind rollers beyond the edge of the blind, and secured thereto in such a manner that a pull on the cord (or on the rollers or blind) will rotate both rollers in unison, and wind the blind on to one or other of the rollers, according to the direction of the pull on the cord. There is also a device for imparting movement in either direction to the cord, or to either of the rollers or the blind." J. E. Thornton, Rokeby, Altrincham.

New Book.

"Jahrbuch des Photographen, 1905." Edited by G. H. Emmerich. Published by Gustav Schmidt, Berlin. M. 3.50.

A review of technical progress, formulæ, tables, and industrial statistics occupy almost one half of the 500 closely-set pages of this "Jahrbuch." German patents of the year, and addresses of photographic schools, societies, and the trade make up the other half. The mass of facts is clearly arranged.

BEFORE the Society of Arts on Wednesday, 8th inst., at 8 p.m., Mr. R. Child Bayley, F.R.P.S., will lecture on "Time Development in Photography, and Modern Mechanical Methods of Carrying it out." Mr. George Davison will preside.

BRITISH Astronomical Association.—At the monthly meeting of the British Astronomical Association, held at Sion College last week, Mr. A. C. D. Crommelin, F.R.A.S., the president, who was in the chair, said that they had had an astronomical disappointment. Announcement had been made of the discovery of a sixth satellite of Jupiter, far distant from the others; and after the discovery of Phoebe, the ninth satellite of Saturn, it was thought to be very probable that this was a genuine discovery. Since the original announcement was made it had been suggested that the object might be an asteroid; but it was observed for a month at the Lick Observatory before being announced, and it was very improbable that an asteroid would hang about Jupiter for so long. However, last Tuesday they learned by telegraph that at Heidelberg Professor Wolf had discovered by photography a minor planet near Jupiter; and on that day a further telegram had been received giving the motion of the planet relative to Jupiter. It seemed probable that this was the same object as that seen at Lick; if so, the idea of the object being a satellite of Jupiter was impossible, for its motion was too rapid. It was evidently a minor planet. Should this identity be established it would be a great disappointment, because the retrograde motion of the ninth satellite of Saturn was quite a new feature in the solar system; and a distant satellite of Jupiter would have either confirmed or contradicted, as the case might be.

New Materials.

The "Wellington" Plates. Made by Wellington and Ward, Elstree, Herts.

In placing upon the market a series of plates Messrs. Wellington and Ward take a step which lays upon them the weight of new responsibilities. For ten years past they have appealed to photographers as specialists in the manufacture of flexible sensitive materials—paper film, bromide, P.O.P. and gaslight papers, celluloid film, and carbon tissues. It is no exaggeration to say that in this field they have shown themselves manufacturers of products which are not only of high and uniform excellence, but in many instances possess distinctive qualities. Hence it is that their entrance upon a new branch of manufacture forces upon them the obligation to maintain a notably high standard, as it raises expectations among those who are already familiar with their wares. Our readers will doubtless have these facts in mind, as we had in making trial of the new plates.

The "Landscape" brand is a plate of medium rapidity, marked at 100 H. and D., and sufficiently rapid for a large proportion of ordinary work. We do not hold the view that a slow or medium plate should be chosen in preference to a more rapid one, for that rule of the ancient authorities has been robbed of its value by the modern achievements of the emulsion-maker, but those who take this position ought to be satisfied with the clean working of the "Landscape" plate, which is rapid enough for hand-camera work in good weather.

The "Speedy" is a plate of extreme rapidity, marked by the makers as 250 H. and D., and fully as sensitive, in our judgment, as this figure indicates.

For these, and for the other plates, the developers recommended by Messrs. Wellington and Ward are pyro-ammonia and pyro-soda, the latter according to the following formula:—

No. 1.

Pyrogallie acid	1 oz.
Sulphite of soda	2 oz.
Citric acid	40 gr.
Water to	10 oz.

No. 2.

Carbonate of soda	8 oz.
Sulphite of soda	8 oz.
Water to	80 oz.

For studio work take 1 oz. of No. 2 and $\frac{1}{2}$ dr. of No. 1, with water 1 oz. For normal work take 1 oz. of No. 2 and 1 dr. of No. 1, with water 1 oz.

The "Iso Speedy" should prove the most interesting of this group of plates, as it bears an emulsion which possesses notable orthochromatic properties. It is customary to describe the quality of a colour-sensitive plate in somewhat vague terms, such as describing the rendering of a landscape in full foliage on a plate exposed under unspecified conditions. In the absence of foliage at the time of writing, and in order to give a degree of definiteness to our description, we give the results of tests of the "Iso Speedy" made by Mr. C. E. Kenneth Mees, B.Sc. The measures of sensitiveness found behind Eder's blue and yellow screens are:—

$$\frac{\text{Blue sensitiveness}}{\text{Yellow sensitiveness}} = \frac{1.75}{1}$$

An average ratio, Mr. Mees writes, for a good erythrosine plate is $\frac{15}{1}$; for a good panchromatic plate $\frac{5 \text{ to } 6}{1}$. The ratio of 1.75:1 of the "Speedy Iso" thus shows it to possess extremely high yellow sensitiveness, and this quality is plainly seen in photographs of the arc-light spectrum which we have made. The region of maximum density falls in the yellow to yellow-green part of the spectrum between D and E. The improvement in yellow sensitiveness effected

by the sensitising dye as measured by Mr. Mees is to increase it about seventy times.

Another property of the plate, which is plainly shown from Mr. Mees' series of tests, is the speed with which the plate develops. The figure, measuring its speed of development (with ferrous oxalate), is very high, as high as one usually obtains with slow landscape plates, with the result that with a development factor of 1 the time of development is 2min. 50sec., whereas the average time for a plate of this kind is from six to eight minutes. These results, we think, may be taken as showing that Messrs. Wellington and Ward offer a material which has distinctive qualities of its own, its character—to sum up in a few words—being the conjunction in one plate of intense orthochromatic quality, general sensitiveness, and great speed of development.

We must add that all the above brands of plates are sold at prices uniform with the popular shilling per dozen in quarter-plate size. The notice of a photo-mechanical and a lantern plate must be deferred until next week.

The "Well" Developing Dish. Made by Taylor, Tunnickliff and Co., Ltd., Hanley, Staffs.

By providing, at one end of the dish, a well large enough to hold developer for about one dozen plates, the makers obviate the return of the solution to the cup or graduate as each plate is developed. The plate, it will be seen from the figure, is most easily removed from the dish. To keep it evenly covered with liquid during development it

is necessary to rock the dish gently during the whole time, that is to say if only enough developer to fill the well is employed. But if development has to be prolonged, enough solution should be added to cover the plate when the dish is level. In handling a batch of plates which develop up quickly we have found the dish most convenient, and, with the precaution we have mentioned, it is just as suitable when patience is called for in dealing with under-exposure. The dish is made in quarter, 5 by 4, half, and whole plate sizes, the respective prices being 1s. 6d., 2s., 2s. 6d., and 3s. 6d.

The Sinnox Daylight-Loading Camera for Glass Plates. Sold by Marion and Co., 23, Soho Square, London, W.

A system of transferring the purchased box of plates directly into the camera for exposure may be reasonably sure of a warm welcome from a large class of amateur workers. Old hands may not regard the dark-room in the light in which our young friends—young in photography, if not in years—look at it, as the bugbear of an otherwise delightful recreation. The fact remains that "without a dark-room" is a phrase to conjure with, and Messrs. Marion can therefore claim attention for the system under which the photographer thrusts the box of plates into his camera as he leaves the dealer's shop, and is straightway ready for his exposures.

The "Sinnox" camera achieves this in a very simple way. Each plate is supplied in a cover of black paper, and when the packet of half a dozen is placed in position in the camera (fig. 1) it is only necessary to insert a pin into the first of six holes (fig. 2) and to draw off the outer case of the packet under cover of the chamber marked T

in fig. 3. Plate No. 1 is then ready for exposure, and in the same way, inserting the pin in holes 2 to 6, the remaining five plates are exposed. The packet is now removed, and can be sent off for development or developed like any other plate—in a dark-room.

The changing device, in our experience of it, has proved most reliable, and, altogether apart from daylight-loading, seems to possess the elements of regular working. The cameras at present embodying the "Sinnox" system are four in number, two for plates $3\frac{1}{2}$ by $2\frac{1}{4}$, and two for quarters. The prices range from 31s. 6d. to 60s., whilst plates of H and D 200 cost 1s. per half dozen in the quarter-plate size. The "Sinnox" price list fully specifies the cameras, and is obtainable from Messrs. Marion.

Fig. 1.

Fig. 2.

Fig. 3.

Messrs. Raines and Co., Ealing, London, W., send us their 1905 list of prices for enlargements and all other kinds of trade work. Though it runs to but forty-eight pages, it catalogues an immense variety of products, for Messrs. Raines are ready to do anything in the way of printing—from stamp photos to enlargements in life size, from a single carbon miniature on ivory to the entire printing of a studio; also to half-tone blocks and frames of all kinds. The list itself, excellently illustrated in half-tone, speaks for their work, though their reputation, as it is known to us and many others, stands in no need of such testimonial. Nevertheless, when much trade printing is of a kind to bring discredit on photographers, there is cause for satisfaction in the high standard which is maintained by the more scrupulous firms. If we could, we would show our readers a piece of carbon enlargement by Messrs. Raines which comes to our notice as we write. Apart from financial success, there may be legitimate pride in producing such work.

The Holborn Negative Posting Box. Sold by Houghtons, Limited, 88-89, High Holborn, London, W.C.

A box specially designed to secure safe transit of negatives through the post is now supplied by Messrs. Houghton, and ought to be

found useful by professionals in their dealings with enlargers and printers. The box is provided with felt pads, between which the negative is pressed when the lid is screwed down. As the screws work in brass bushes, the box can be used over and over again. In half-plate size the box costs 1s. 8d.; in quarter-plate, 1s. 4d.

W. Butcher and Sons, of Farringdon Avenue, have placed on the market a neat little printing gauge or actinometer, consisting of a numbered and graduated scale of densities, at the price of 1s. 9d. for three, so that one may be affixed to every printing frame. P.O.P. is the sensitive paper recommended for use with it.

A Pocket Gas Lighter. Sold by Townson and Mercer, 89, Bishopsgate Street Within, London, E.C.

Workers in dark-rooms ought to appreciate this convenient pocket edition of the old Dobereiner's lamp. No larger than a pocket pencil-

case, it may be carried on a key-ring or chain, and is stated by the makers to last for six or nine months without recharging. Applied to a gas burner, ignition takes place very rapidly. We can imagine that one of the lighters, which costs 1s. 6d., hung by a string in the dark-room, will render needless the question: "where are the matches?"

THE death took place at Inverness on January 20 of Mr. David Whyte, photographer, after a prolonged illness. Mr. Whyte carried on an extensive business in Inverness for about thirty-five years. He had the honour of photographing the late Queen Victoria and the present King and other members of the Royal Family. The deceased was 62 years of age, and is survived by a widow and family.

A CAMERA for Architectural Photography.—In the current "Journal of the Camera Club," there is a report of the paper by Professor Flinders Petrie, an abstract of which appeared in our issue of November 4, 1904. Professor Petrie uses for his architectural work in Egypt and elsewhere, a pattern of swing-lens camera, in which the lens can be tilted through an angle of 45 deg., while the plate is kept parallel with the architectural elevation. The camera was designed chiefly for telephoto work, and among the points of novelty claimed for it are:—Tripod attachment of the lens to the plate. Free motion of a base arm to 45 degrees vertically and horizontally from the normal. Use of a single clamp screw to secure (1) the lens carrier upon the base arm, and also (2) the ball and socket rods for fixing the tilt and skew. Use of compound spirals of wire and covering bag, instead of bellows. Use of plate box under the camera; and feed by putting flat films into the grooves of the ground glass, without any carrier. Graduations of the base rod into scale of proportion of the image to the object, as well as distances.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Feb.	Name of Society.	Subject.
6.....	Camera Club.....	Exhibition of Members' Lantern Slides.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MEETING held January 26, 1905, at the White Swan, Tudor Street, E.C.; Mr. A. E. Smith in chair.—Mr. R. J. Kindon exhibited a lens named the "Ocular," the peculiar feature of which is the fact that on pressing the bulb to open the shutter one of the lens components is set in motion. It was claimed that in portraiture this motion does away with the need of retouching. The movement of the lens is adjustable to the shutter exposure requisite for the time required to give a fully exposed plate.

In the "Stigmat" lens for landscapes, etc., the whole of the lens moves, and this motion renders possible the use of the full aperture f/6.2 for all purposes, the depth of focus obtained being marvellous.

Messrs. Zimmermann, 9 and 10, St. Mary-at-Hill, have the lenses fitted to cameras for the inspection of any one interested in what is quite a new departure.

Mr. Freshwater gave an exhibition of microscopic objects projected by means of the optical lantern worked by his son. The chairman remarked that he had seen such exhibitions on previous occasions, but never of such a high degree of perfection. In reply to questions, Mr. Freshwater stated that the apparatus used was the same that he made all his micro enlargements with, and handed round and explained various parts.

CROYDON CAMERA CLUB.

JANUARY 25.—The annual general meeting was held, and passed off in peace and quietude, a condition of affairs which by no means prevailed at the annual meeting preceding it. This was not due, as had been somewhat unkindly suggested, to the fact that a cautious Hon. Secretary had engaged a police constable as caretaker, for this

guardian of the law had, for reasons best known to himself, left shortly prior to the meeting. The real explanation of the general harmony is that there was nothing to quarrel about. Every one agreed that in Mr. H. M. Bennett, the Society had an ideal Honorary Secretary, and that the retiring President, Mr. S. H. Wratten, might in future be equalled, but not bettered. A large influx of new members have characterised their joint reign, and there is no doubt the general standard—if one may use such an expression for want of a better—has steadily risen. Certainly no individual members should be in want of authoritative information and guidance, for among the roll are plate makers, photographic paper manufacturers, research workers (two of whom, Messrs. Mees and Sheppard, have already made a name for themselves), practical technical photographers of ability, and last, but by no means least, advanced pictorial workers, firm on "gum" and warm on "boiled bromides." The fixture list has been a strong one, members largely contributing, in many cases, original papers and descriptions of new processes. The move to larger and better premises has been distinctly one in a right direction, and it speaks well for the club that considerably over £50 was immediately subscribed to cover its cost. The annual exhibition was one of the most successful ever held, in all respects, except from a financial one. Notwithstanding this, the club's funds are in a healthy condition.

The business of the evening resulted in Mr. W. H. Smith being unanimously elected to the Presidential chair, and Mr. F. W. Hicks to the somewhat ungrateful post of treasurer, both elections being signalled by loud applause. Mr. W. H. Rogers, an old and valued member of the Council, rejoins it, and Messrs. Bawcomb and Wood appear thereon for the first time.

The usual and inevitable votes of thanks to officers, and all and sundry, terminated the evening.

SOUTHAMPTON CAMERA CLUB.

THE members of this club who attended the lecture at the club-room, on Monday evening, by Mr. E. Harvey Piper on "Our Chapter Houses," formed an audience which, though an intensely enthusiastic one, was quite inadequate, numerically, to the merits of the lecture. Having by a specimen plan shown the general placing of the chapter houses in the various abbeys and cathedrals, the lecturer explained the two chief forms of construction in the oblong and polygonal styles, and then proceeded to make the round of the chapter houses, with the aid of the slides of many noted architectural workers, among whom Mr. F. H. Evans figured largely. Beginning first with the houses in the oblong style and following chronological order, Mr. Piper went first to Gloucester, with its Benedictine origin, and spoke of its connection with Domesday Book and Richard, and then dashed off to Durham, speaking in scathing terms of the vandal architect who destroyed by explosives the beautiful apse, and recording how the beautiful work had recently been restored as nearly as was possible. Winchester was next visited, the features so well known to the club members being pointed out; and then came Bristol, with its wonderful house, the finest conception of Norman work, according to the lecturer, in the land. Then came Ripon, stern and stately, with its story of the men who broke sanctuary, and again a local instance in old Beaulieu. The lecturer told again the story of King John and the Abbots, and then came still closer home to poverty-stricken Netley, whose establishment at the period of the dissolution was twelve brethren only, and whose only literary treasure consisted of one small volume. Here it was pointed out how the forbidding of the introduction of the figure into the sculpture had resulted in the exquisite geometrical designs, and how the very repression had resulted in the extension of the art. Furness Abbey, Exeter, Rochester, and Canterbury were visited in turn, and then the lecturer came to

the polygonal chapter houses, among which are Worcester, Lincoln, Lichfield, and Westminster.

Throughout the lecture Mr. Piper had been guide, artist, poet, and the eloquent enthusiast; and the vote of thanks passed on the proposition of the President, Mr. W. B. Hill, was of the very heartiest description. Mr. Piper was not permitted to leave until he had promised a further lecture, which will be eagerly looked forward to.

A SOCIETY called the Oliver Goldsmith Photographic Society has recently been formed by the members of the photography class at the Oliver Goldsmith Commercial School, Peckham Road. In addition to the ordinary meetings on Thursdays, practical instruction in photography is given on Tuesdays and Fridays from 7.15 to 9.45 p.m. by Mr. F. W. Bannister. Non-students, however, will be cordially invited as members of the society, and any one interested may obtain full particulars by writing to the secretary, Mr. F. Tomlinson, 63, Montpelier Road, Peckham.

Commercial & Legal Intelligence

B. J. EDWARDS AND CO., LTD. (Photographic Material Manufacturers, Ealing).—Announcement is made of issue on January 7 of £700 2nd debentures, part of a series created April 12, 1902, to secure £8,000, charged on the company's undertaking and property, present and future, including uncalled capital. Total amount previously issued of same series, £7,000.

G. B. KENT AND SONS, LTD.—The report of directors and accounts for the year ended September 30 states that £5,365 is available for the ordinary dividend. The past year has been one of severe depression and keen competition, added to which the prices of nearly all raw materials used in the brush trade have advanced. The life directors therefore forgo their fees. The board have placed £500 to reserve (making £2,500) and paid the usual half-yearly dividend on the preference shares. In addition, they have written off one-third of the balance of equipment account of the new factories, and recommend a dividend at the rate of 6 per cent. per annum on the ordinary shares for the second half-year (making 5½ per cent. for the year), leaving £254 to be carried forward.

AN Architect's Light.—Is an architect legally entitled to an extraordinary amount of light for the purpose of carrying on his profession? This was the main issue in a special case, stated by an arbitrator, Ambler v. the Bishop of Leeds, which came before Mr. Justice Bray last week. Mr. Ambler is an architect carrying on business in Cookridge Street, Leeds, and opposite his premises a Roman Catholic cathedral is being erected. Mr. Ambler complained that the new building obstructed his light, and threatened an action, but after negotiations arbitration was resorted to. The arbitrator found that in spite of the building there remained sufficient light for all ordinary purposes, and that the plaintiff was not entitled to damages for interference; but if, on the other hand, a court of law found that he was entitled to an extraordinary amount of light, he assessed the damages at £600 odd. It was now argued, on behalf of the plaintiff, that user for twenty years and the nature of his profession entitled him to a special amount of light. His lordship decided that this was not so. A person carrying on a delicate trade, he held, was not entitled to a greater enjoyment of light than other persons. In this case there was, therefore, no actionable obstruction; the plaintiff was not entitled to damages, and there must be judgment for the defendant.

COPYRIGHT in Post-Cards.—In the City of London Court a point of interest in regard to the sale of picture post-cards was disposed of on Monday last. Mr. Frank D'Arcy, photographer, 90, Grafton Street, Dublin, sued Mr. Frederick Hartmann, 45, Farringdon Street, E.C., for £34 1s. 6d., for seventy-one photographic negatives of views in and about Dublin and Killarney, supplied for the purpose of enabling the defendant to reproduce them as coloured picture post-cards. Defendant raised a counter-claim for damages, and said he had bought the exclusive right of reproduction, and now found that the plaintiff had sold other negatives of similar views to rival reproducers. Plaintiff stated that he had sold many prints made from the same negatives before he sold them to the defendant. Some of the negatives were fifteen years old. The copyright in the negative did not transfer until the purchase. It was not retrospective. In fact, he did not sell the exclusive right of reproduction. Some of the negatives took days to obtain, and the exclusive right to reproduce them could not be sold for 10s. 6d. each, the price charged to the defendant. He could take any number of negatives at the same time of the same view, and sell each separately. Defendant said he thought he was getting an exclusive picture. Judge Rentoul, K.C., found for the plaintiff on the claim and counterclaim, with costs.

News and Notes.

THE current list of "Elge" films reaches us from Messrs. L. Gaumont and Co., 22-27, Cecil Court, London, W.C.

A SALE of cameras and other apparatus is announced by Messrs. Houghton. It is to last for about a fortnight from the present date and lists will be sent on application.

THE card-catalogue of the Derby Photographic Society appears this year in its accustomed handsome shape, and fulfils its mission, we hope, of keeping the society fixtures constantly before the members.

NEW Thornton-Pickard specialities are listed in the 1905 abridged catalogue which the Thornton-Pickard Co. will send to any applicant. It describes the "Rotator," a new 30s. magazine hand camera which will be ready in March, a new triple extension focal-plane stand camera, and other apparatus.

FANCY DRESS BALL.—The employees and guests of Mr. J. F. Lessels, photographer, Aberdeen, were entertained last week at a supper and fancy dress ball. Twenty-five couples were present. An interesting function took place at supper, when Mr. Spencer, on behalf of the employees, presented Mr. Lessels with a handsome dressing-case as a token of esteem. The dresses of the company—historical and fancy—were exceedingly striking and effective. The host made a life-like David Garrick while Miss Lessels as Lady Hamilton was quaintly pretty.

THE camera must be included in the outfit of the up-to-date Parliamentary speaker. During the recent election in North Dorset a Free Trade meeting held in the Blandford market-place was continually interrupted by a number of Tariff young gentlemen. Mr. Outhwaite, who was speaking, stood it for some time, then called attention to them as specimens of latter-day reformers, and said he thought if he got his camera a photograph of them would do for the Free Trade journal; and at that moment he left the improvised platform. The ruse succeeded: the threatened camera induced the interruptors to take cover among the general crowd.

THE case of Herbert Meek, mentioned last week, came before the Brentford magistrates on Friday last, when it was stated for the prosecution that the accused was engaged as general manager to the

company on September 1, 1904, at a salary of £2 10s. per week. After he left on December 24, the prosecutor examined the books, and discovered certain irregularities, it being alleged that sums totalling £2 7s. 9d. had been received by Meek but not accounted for. After leaving the company's employ, the accused, it was stated, represented that he had been given permission to borrow the camera, whereas no such permission had been given. Mr. Wilfrid Firth submitted that the whole question was simply one of account, which could have been settled in a civil court. The Chairman (Mr. C. J. Cross) said there was not sufficient evidence to send the case for trial, and the accused was thereupon discharged amid applause in court.

DEATH of Mr. G. R. Baker.—We regret to announce the sudden death of Mr. G. R. Baker, who for thirty years past was connected with Messrs. J. H. Steward, opticians, of 406, Strand. Mr. Baker, who was fifty-five at the time of his death, was ill for only a few days last week, and succumbed on Saturday, the 28th inst., to influenza, pleurisy, and pneumonia. His interment took place on Wednesday last at the Brompton Cemetery. He leaves two daughters and four sons, one of whom is in business in Cape Town. The deceased gentleman will be missed by many friends, for he was widely esteemed for his genial qualities. Readers of the JOURNAL will remember him as a constant contributor to the "Lantern Supplement," and as one always ready to help others out of his wide experience of lantern matters.

DEATH from Potassium Cyanide.—Mr. W. Schroeder concluded an inquest at St. Pancras on January 18 on the four-year-old boy of a photographic printer, living in Bayham Street. The child was a hopeless imbecile, and on January 12 he took out a drawer from a chest in the room in which he was tied to his bed-end by a rope, and opening an unlabelled tin, containing cyanide of potassium, ate a quantity of the poison and died. The father said he did not sign the "poison book" when he bought the potassium cyanide, as he frequently went to the shop and obtained all he wanted as a wholesale customer. The Coroner referred to the freedom with which people on any pretext were able to purchase deadly poisons, and said that he was not satisfied that a chemist who sold 2 oz. of potassium cyanide, even to a regular customer, could take refuge under wholesale trading and not require the purchaser to sign for it. To allow such a practice to obtain would practically mean the sanctioning of wholesale destruction of life. The jury found that the child died from misadventure. They added that there was carelessness on the part of the parents, and that the sale of such poisons as potassium cyanide should be restricted.

"NATURE STUDIES," portrayed by the camera, has been the subject of the third one-member's show of work at the clubroom of the Tunbridge Wells Amateur Photographic Association. The exhibitor was Miss Turner. There were 105 pictures exhibited, which have been selected from the work done during the last three years. The Broads, in the Eastern counties, claim a large share of her attention, as proved by the wild fowl and their nests of that part, which were shown. There must be a great fascination in securing a negative of that rare bird, the great crested Grebe, on its nest, and it must be borne in mind that on these occasions it is frequently necessary to be hidden from the view of the bird, covered up with rushes or other matter, perhaps in a cramped position, and at times irritated almost beyond endurance by the interminable midges, so that it can reasonably be understood, when a successful rendering has been secured, how much store is set on the negative thus obtained. Amongst other pictures were nests of the teal, mallard, reed bunting, shoveller (and a view of the latter showing how the parent birds cover it up when leaving it), swans, lapwing, blue tit, cole tit, whin-chat, water-rail, and black cap.

Correspondence.

THE ROYAL PHOTOGRAPHIC SOCIETY.

To the Editors.

Gentlemen,—As a London member, and one fairly in touch with the R.P.S., and a constant attendant at its meetings, may I ask by what authority the opening sentence of the report is made: "The election of President and Council of the R.P.S. appears to be causing more than the usual amount of interest on the part of the members"?

Till the idea for this meeting was mooted I had not heard a word—either in the house of the R.P.S., or outside amongst its members—on the subject; there certainly was not "more than the usual amount of interest."

If all I hear is true, the selection of the candidates resolved itself into somewhat of a farcical procedure, which may be briefly described as "you scratch my back, and I'll scratch yours." Mr. A. (present at the meeting) proposed Mr. B. (also present), Mr. B. proposed Mr. A., Mr. C. (present) proposed Mr. D., and Mr. D. reciprocated, and thus went on the merry little game.

As one of the members of the Reform Committee of 1902, I should like to ask why it must be resuscitated, it did its work and died the natural death; and what is the particular status to which the Society is to be raised from or to?

There is an old saying that a house divided against itself cannot stand, and it is a matter of regret that a self-elected committee or body of members should band themselves together to keep open a sore that was caused three years ago, and split the Society into cliques and parties. Surely if the members at large, or individually, are so dissatisfied with the work of the existing Council they can of themselves elect a new one, in part or in whole; but so far as I am concerned, to have a list such as published thrust upon me is as nauseous as a dose of medicine, and I shall exercise my right to support as few of its members as I like.—Yours faithfully,

FELLOW OF THE ROYAL PHOTOGRAPHIC SOCIETY.

London.

To the Editors.

Gentlemen,—As a country member, may I be allowed to ask either Mr. Churchill or any other member who was present at the meeting in the library of the R.P.S., as to the reason for the agitation which they are fomenting, and why should I vote for the list of nominees on p. 78 of your last issue. Some of them are utter strangers to me, and so far as I can see there is not a single professional photographer's name on the list.

Is the professional photographer not wanted in the Society, and is it to drift into a purely amateur shop?—Yours faithfully,

PROFESSIONAL.

Edinburgh.

To the Editors.

Gentlemen,—With reference to the letter from Mr. Churchill, we should much like to know—(1) Who constitute the "Reform Committee"? (2) Who appointed them? (3) What they want to "reform"? If my brother and I met by the cosy fireside in the library at Russell Square, and appointed ourselves "Reform Committee No. 2," should we be justified in endeavouring to coerce the society by seeking publication for our resolutions and threats of "opposition," "activity," and "force," as if we were the only members who knew how "to raise the status and membership" of the

society, or at least the only ones in whom the knowledge was associated with the requisite "activity" and "force"?—Yours faithfully,
F.R.P.S.

VIEWING STEREO PICTURES WITHOUT A STEREOSCOPE

To the Editors.

Gentlemen,—I was much interested in a paragraph in your issue of November 11, "Viewing Stereo Pictures without a Stereoscope," and shall be much obliged if you will refer to this again and give further particulars. If possible, print Mr. Violle's paper in full, as it would probably interest many of your readers.—I am, Sir, yours faithfully,

H. R. HEARSON.

Shanghai, December 24, 1904.

[Except that M. Violle uses a pair of lenses in taking his negatives, his process does not differ from that of Mr. F. E. Ives, who originated the method, and gave the results the name of "Parallax Stereograms." Mr. Ives' paper appeared in full in our issue of January 1, 1904.—Eds. B.J.]

GUM PRINTS FOR SOCIETIES.

To the Editors.

Gentlemen,—It might interest secretaries to know that I have a small collection of about twenty frames of gum prints, which I should be pleased to loan for exhibition or society gatherings.

The idea in the arrangement is to show the wonderful range of the process of gum, unattainable in any other medium.—Yours, etc.,
January 27, 1905.

J. PAGE CROFT.

HONORARY PHOTOGRAPHERS.

To the Editors.

Gentlemen,—A day or two ago I received the enclosed circular letter.

A similar "dodge" was tried some few years since, and the photographers who consented to take "beautiful photographs" for nothing soon discovered that the scheme, as far as they were concerned, was an utter failure.

The possible advantage to the photographer, even in the case of a high-priced periodical of importance, would be very problematic, but when it is a question of three coupons cut from a penny weekly magazine the value placed upon the "beautiful photograph" by the recipient may be readily guessed.

Such a communication is an insult to the profession, and should be treated with the contempt it deserves; and I sincerely hope none of my professional brethren will lend themselves to a scheme by which a large publishing firm seeks to be generous and increase the circulation of a magazine at their expense.—Yours truly,

Dalston Lane, London, January 30, 1905. F. A. BRIDGE.

The circular-letter runs as follows:—

"Woman's Life," Southampton Street, Strand, London, W.C.,

January 27, 1905.

Dear Sir,—During the next few weeks, and for a limited time, we are publishing in the pages of "Woman's Life" an announcement of a free photograph scheme, brief particulars of which are enclosed. In connection with this scheme we are desirous of giving your name and address as the photographer specially appointed by us for your district.

As you will observe, we state that you will be prepared, on presentation of three "Woman's Life" photograph coupons, to take a cabinet photograph of any of our readers without charge. You will, of course, readily perceive that this introduction by us paves the way for further remunerative business on your part, for it is most likely that in the event of a successful photograph resulting from the preliminary sitting, our readers would be desirous of purchasing at your usual charges further prints, enlargements, etc.

Your name and address will be duly announced in the pages of this paper, and with our large circulation it is expected that a great number of readers in your district will call upon you.

If you are agreeable to take one photograph of any reader presenting three coupons, as set forth in our scheme, without charge, will you please write to me by return, and your name shall be included in our list without delay?—Yours faithfully,

J. G. P.

For the Editor,

"Woman's Life" Presentation Photographs.

A new scheme that will interest every reader.

We have made arrangements with the photographers whose names are published here to take a cabinet photograph of yourself in exchange for three of the coupons shown below. Beyond this nominal fee there is no charge.

Three of these
Coupons entitle
you to a beautiful
photograph
either of your-

COUPON.

self, your husband,
your sweetheart, your
baby, sister, or
friend.

The photograph will be cabinet size, well taken, and handsomely mounted. Remember, no payment is necessary.

This week we publish the names of London photographers who have been appointed by us to take these free photographs. Next week our Manchester readers will be given an opportunity of securing a splendid photograph, specially taken, in exchange for three coupons in next week's issue.

List of "Woman's Life" Photographers.

ENTRIES for the South London Photographic Society's annual exhibition close on February 18, 1905. Entry forms can be obtained from the Secretary, H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

PHOTOGRAPHING Fish.—One of the most interesting portrait galleries in New York, and one not generally known, is the roof garden studio of the big aquarium at the Battery. Here on bright days, says the "New York Tribune," certain of the fish, the most characteristic and representative of their respective species, are brought out from their exhibition quarters and photographed. A specially-devised narrow glass tank, with unusually transparent surface and pebbly bottom, is used for holding the fish during the picture-making time. This novel fish studio is in charge of the former superintendent, Mr. L. B. Spencer, who now conducts the nature study department in the laboratory, which was visited last year by 2,620 persons, including students. The desired fish are brought to the roof from the exhibition hall in large buckets filled with salt or fresh water. By the aid of a scoop net the fish is gently dumped into the waiting glass case. Here his movements are watched, and when a favourable attitude is struck, such as a free swimming one, with whole body outlined, the exposure is made. Quick plates, a rapid lens, coupled with an extremely short exposure, ranging from one-hundredth to one five-hundredth part of a second, are necessary to produce a fair image. Some of the large and showy fish, such as the carp, fourteen inches long, owing to their slow swimming gait, are comparatively easy subjects to portray. Of all the colony of queer boarders in the aquarium, probably the little sea horses are most popular with visitors. Reproductions of these for pictorial books and for "slides" used in school work are in great demand. Mr. Spencer has tried on a number of occasions to catch these fantastic creatures, but their frisky mood in nearly all instances has baffled his securing good and distinct facsimiles.

Answers to Correspondents.

* * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.

* * * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPH REGISTERED:—

C. Foster, Promenade, Port St. Mary, Isle of Man. Photograph of Dr. Torrey addressing the Members of the Corn Exchange, Liverpool.

H. C.—The "Optical and Cinematograph Journal," published monthly by E. T. Heron and Co., 9 and 11, Tottenham Street, W.

R. C.—An article dealing with the mercury lamp commences on p. 85.

Miss J. S. (Paris).—We have none. If you address the British Commissioner of the St. Louis Exhibition, Westminster, London, he may be able to supply you with official reports.

F. W.—We should strongly advise you to patent the camera and then apply to some of the leading houses, whose addresses you will find in our advertisement columns or in the BRITISH JOURNAL ALMANAC.

FERROTYPE DRY PLATES.—Can you give me any formula for the sensitizing of dry ferrotype plates which will keep?—W. ELLIOTT.

Ferrotype dry plates are, we believe, coated with a collodion-bromide emulsion, formula for which will be found on pp. 1,046-1,047 of the B.J. ALMANAC for 1905.

LIPPMANN PROCESS.—I shall esteem it a favour if you will kindly give me particulars as to where I can obtain all information of the Lippmann process of colour photography.—A. H. P.

"Photography in Colours," by Bolas, Tallent, and Senior, published by Marion and Co., Soho Square, price 5s., is the best work.

PUBLISHERS WANTED.—In the query column of the Journal of January 13 you recommend a book called "The Pose in Portraiture," No. 2 of the Photo-miniature series." I have tried to get this through a good local bookseller and he cannot get it. Could you please tell me the name of the publisher?—W. F. BATE.

Dawbarn and Ward, 6, Farringdon Avenue, E.C., are the English publishers of the Photo-miniature.

F. H. C.—Unless you have sold the copyrights outright to the post-card people, you can register them now quite apart from your arrangements as to acknowledgment. But as to stopping publication, that we cannot say, because we do not know what arrangement you have made with the publishers. If you received nothing beyond the acknowledgment, certainly you can stop publication, but otherwise you do not appear to have much of a case.

LIGHT FOR PORTRAITURE.—I should like to know of a light to take miniature photos (not gas). Are there any acetylene generators made that are automatic and safe; if so, who are the makers?—W. E. H.

It is contrary to our rule to recommend the goods of individual firms. We would refer you to the Almanac for the current year, in which you will find the advertisements of several illuminants. Either acetylene or magnesium burnt so as to include the products of combustion will answer well for the purpose.

COPYRIGHT.—We shall be obliged if you will reply per post on receipt to our queries. We paid a certain firm of photographers for taking six photos, all different positions, also we paid a certain gentleman for posing. Can we claim copyright? or have we to have the sanction of the photographer? If we can, what will be the cost to enter each at Stationers' Hall, and what is the *modus operandi*.—G. W. AND Co.

As you have paid the photographers for their work, the copyright is yours, though you must, of course, give the name of the operator as the "author of work." You can register the copyrights at Stationers' Hall or through our own publishers on the conditions stated at the head of this column.

RETOUCHING.—Kindly examine enclosed prints and give me your opinion of retouching on same, and do you think I am improving since the last work you saw of mine?—ANXIOUS INQUIRER.

Your retouching is still very poor and unsatisfactory, and we consider that you are wasting your time in trying to teach yourself this art. Under an expert instructor you would learn more in one month than you would teach yourself in many years. Your methods are all wrong, and consequently you have no "touch," and show but feeble efforts in the direction of modelling. If you cannot get first-class instruction (and any other is quite useless) locally, we advise a course of postal lessons.

COPYRIGHT.—I have a photograph of a cathedral from a somewhat unusual point of view, which I think is worth copyrighting, and shall be much obliged if you will tell me exactly how much protection it would afford me. I am selling the view, and am naturally anxious that it should not be copied.—SIGMA.

Under the Copyright Act you can obtain protection in your photograph, and can prevent any one from copying it. But you cannot prevent any other photographer from placing his camera in the same position and producing an almost exact fac-simile of your view. "Nothing," says the Copyright Act, "shall prejudice the right of any person . . . to represent any scene or object, notwithstanding that there may be copyright in some representation of such scene or object."

NON-ACTINIC FABRIC.—May I ask if there is a thin, light-safe, easily-carried fabric under which one could change plates safely away from home—say in corner of old roofless building. The fabric might be thrown over one like a curtain, and plates changed under it in the box in which things are carried. A fabric transmitting enough ruby light would be best, but, failing this, a small kind of window might be cut in it. It would require to be a fairly large curtain; consequently thin, yet light-safe.—CURTAIN.

You can obtain ruby fabric from the dealers, and this alone, or silesia lining with a ruby window, may answer your purpose. But why go to all this trouble when you can purchase a reliable changing bag for a few shillings? With it you can change plates in safety anywhere, which you will certainly be unable to do by the method you contemplate.

PHOTOGRAPH ON COPPER.—Many thanks for answer, but it is not what I require. What I want to do is to photograph some designs on to copper plates as a guide for the engraver to work upon. If you can let me know the name of book which gives instructions, and where to obtain same, shall esteem it a favour.—APPROPOS.

It would be possible to transfer a collodion positive or carbon print on to the copper, but as a substratum would have to be used, this might possibly give trouble to the graver. The best thing to do would be to use the enameline process, as used for making half-tone blocks and print direct on to the copper.

It might be possible also to utilise the principle of mercury by bleaching a bromide print in mercuric chloride, well washing, and then squeegeeing down to the copper, when the mercury should attack the copper, giving a faint but distinct image.

SEPIA SENSITISER.—**COPYRIGHT.**—1. Could you give a formula for an preparation in the shape of a sensitising liquid which brushed on to paper gives a pleasing sepia tone without any toning bath? 2. Does copyright obtained in England hold good for the Australasian colonies.—SEPIA.

1. Dissolve 55 grains of silver nitrate in 4 to 5 drams of distilled water. Add ammonia drop by drop to just re-dissolve the white precipitate, and then add (very cautiously) weak sulphuric acid until the odour of the ammonia entirely disappears. To the solution thus obtained 40 grains of green ferric ammonium citrate, dissolved in 6 drams of water, is added. The sensitiser keeps well in the dark. 2. British copyright extends to all the colonies, under the Berne Convention, but we understand that legislation is somewhat lax in some colonies. We note, with thanks, your information as to the Australian Philosophical Institute.

COPYRIGHT.—On our September holiday, 1904, I specially took a series of photos of a well-known person. Several weeks before I had arranged with him to do so, and had considerable difficulty in making arrangements, as several persons had also to be consulted. The photos turned out well, and in return copies were presented and received with thanks. No money was paid to me for taking them, but fully a month afterwards I received an order from one of the parties asking copies and account with them. These I sent on, and heard nothing more of them until to-day. I find three of my photos are reproduced in a well-known magazine, but with false statements under each regarding circumstances under which I took them. Can I claim damages for the following reasons?—(1) Not having been paid to take the photographs. (2) Gave no authority, or was even asked to allow reproduction. (3) When photographs appear they have false and misleading statements under each, and no name mentioned for photographer.—H. S. L.

We think it is clear that the copyright is yours, but you appear to have neglected the very advisable precaution of obtaining a written assignment of it to yourself and immediately registering it. This is the wisest course to pursue in all cases, as it leaves no room for argument as to whether the photographer did or did not obtain a "valuable consideration" for his work. We should advise you to register the copyright at once. Though you cannot claim damages, you can stop further publication and obtain penalties from the infringers.

NOTICE.

Several replies are held over for insertion next week.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

Oxygenated Acetylene. The idea of utilising a mixture of oxygen and acetylene is not new, but the disadvantage is that except in the correct proportions the mixture is extremely explosive; but at the Royal Institution last week Mr. J. Reid showed that by injecting a stream of oxygen into an acetylene flame the brightness was raised from 150 to 2,000 candle-power. Although we have not details as to the particular method employed, it is obvious that a modification of the old blow-through oxyhydrogen jet might be utilised. The possibilities before such an enriched acetylene are, of course, great, and it might be useful not only in the studio, but also for lantern work.

* * *

More Advertise-ment. A week or two ago we quoted the sign of an American photographer: "Time is flying; you will never be so good-looking again. Come in and be taken now." The phrase has inspired an artist of our gay contemporary, the "Sketch," in which we see depicted a woe-begone and presumably mangled motorist deposited before a photographer's premises, on which is displayed an invitation to enter, couched in the terms we have just quoted. The juxtaposition of the printed phrase and the automobilist coiled like the Laocoon among the debris of his vehicle gives a delicious irony to the situation. Photographers who want to attract visitors to their shop windows might do worse than frame the picture and display it for a day or two.

* * *

Alpine Photography. The special photographic difficulties of the class of subject encountered by the Alpine mountaineer are well known to lie chiefly in the

great range of contrasts. It frequently happens that a distant snow-clad peak falls next to a foreground of dark pines, and it is the photographer's task to average exposure and adjust development. A highly tentative method has been adopted in these cases, but Dr. Kuhfahl, narrating his experience of mountain photography in "Photographische Kunst" is in favour of stand development. The plates are retained in the developing solution until the details are visible in the darkest shadows. If the negative is then too dense in the high lights it may be necessary to reduce it with ammonium persulphate, but Dr. Kuhfahl recognises the danger of this operation, and prefers to obviate it by a restrained developer, selecting for this purpose edinol in admixture with acetone sulphite. It was found best to make the exposures on orthochromatic plates through an adjusted yellow screen.

* * *

Coloured Lantern Slides.

Some time ago we commented on the crudity of the vast majority of hand-coloured lantern slides, and deplored the desuetude of an art which, at its best, is one deserving of preservation. We prophesied a revival of the coloured slide as produced by the modern trichromatic process, or hand-coloured by a skilled artist, and there are signs, we are glad to say, that public lecturers and others who seek to amuse and instruct through the medium of the optical lantern, are availing themselves of modern progress in colour photography. But it is particularly regrettable that in instances where the factor of the expense of good hand colouring can hardly be of any account, the most appalling work should be tolerated. In one of the largest of London's music-halls the illustrated song is now a feature. Perhaps twenty slides are employed in accompaniment of a song of five minutes' duration, but in the estimation of anybody with the faintest development of colour sense the slides had far better be left out of the programme. When we hear of the large sums of money paid to music-hall performers, it is legitimate to ask why an audience should be offended by an exhibition of slides so ludicrously crude in their colouring as to destroy any interest in the vocalist's efforts. And the worst of it is that the coloured lantern slide is plunged deeper still in public estimation by such exhibitions.

* * *

Photography and Criminals.

Photography is very largely employed by the police authorities, but is not so much depended upon now, so far as portraits of criminals are concerned, as it used to be. This is not altogether to be wondered at, considering the very poor photography they usually were. They were often taken by, not an experienced portraitist, but one of the

police force, and always in two set positions—one full face and one in profile. These portraits often led to the arrest of an innocent person, and frequently aided the escape of the criminal through the bad likeness. Now the authorities, while still utilising photography, rely more upon photographs of finger imprints—the markings on the fingers of no two persons being, it is affirmed, identically alike. The police have albums filled and classified of thousands of photographs of criminals' finger prints for ready reference. We read that last week some thieves broke into the premises of a bowling green club at Bradford, and made a good haul of wine, spirits, and cash. On one of the spirit glasses a detective found a man's finger mark; this was photographed, and the photograph, when compared with a thousand or more on the file, was found to be identical with one of a man who had passed through the hands of the district police. The man was arrested, and subsequently admitted his guilt. In this way photographs of finger prints often prove of more value than portraits would. A burglar when he breaks into a house does not leave his portrait behind as a means of identification, but he imprints his finger marks, as he frequently finds to his cost.

* * *

"Honorary Photographers."

The letter of Mr. F. A. Bridge, in our last issue, should command the approval of every photographer. Fancy a photographer being asked to produce a cabinet portrait, "well taken, and handsomely mounted," on the production of three coupons cut from a penny weekly paper. This means that by purchasing three penny papers and going with the coupons to one of the "appointed photographers" they are to get a well taken, handsomely mounted portrait for nothing. By buying three dozen of the publication they would be entitled to go to a dozen of the different appointed ones and get a cabinet portrait from each; that is to say, they could obtain a dozen cabinet portraits, in as many different positions, for an outlay of three shillings, and a quantity of waste paper into the bargain, and the deluded photographers who agree to the scheme get nothing at all. In face of this, the alluring statement in the circular "that in the event of a successful photograph resulting from the preliminary sitting, our readers would be desirous of purchasing at your usual charges further prints, enlargements, etc.," is very considerably discounted. Enterprising publishers are very fond of making capital, without remuneration, out of photographers in different ways. One dodge is to offer a few small prizes for the best of a series of photographs, with the right to make use of any that are submitted in competition. By this means they obtain, for a trifling sum, hundreds of illustrations for their publications. It is amateurs who chiefly respond to these enticements. From this last dodge—for it is not the first of its kind—we hope that all professional photographers, for their own credit's sake, and the sake of the profession, will hold themselves aloof, for they cannot expect any profit out of it.

* * *

Frauds on the Public.

A fraud that, we understand, is largely being committed on the public, the victims being mostly servant girls and the poorer classes, has again been brought under our notice, as it is causing great annoyance to many photographers in the suburbs of London. The system is this: A canvasser solicits orders on the so-called coupon system, offering portraits at a very low price if the coupon is purchased. Fairly good specimens are shown, and the coupon bears the address of a photographer whose place

is a long distance off. This part of the business is legitimate enough, as the parties, if they choose to visit the place, can have their portraits taken there on the terms promised, no doubt. But it is here that the fraud and the annoyance to photographers comes in. When the distance to be travelled is demurred to the victim is told that if the purchased coupon is taken to one of the local studios—usually the best in the neighbourhood—the portraits will be taken at the same price, although the regular prices there are perhaps double or three times those mentioned on the coupon. On this promise the money is paid, and the dupe, when he or she goes for the sitting, learns of the clever fraud that has been committed. This, of course, is very annoying to the local photographers, and is made the more so because some of the dupes refuse to believe that they are not actually parties to it. In one of the cases brought under our notice the canvasser persuaded a couple of servants to buy a sixpenny coupon each, telling them that by paying another sixpence at a local studio, where the charge for them was more than three times the price, they would get a dozen midgets—that is, for the shilling. It is a pity these cheats are not brought to book. No doubt most photographers whose names have been thus used would assist in the prosecution if that were instituted by those whose money has been obtained under false pretences.

* * *

Names on Apparatus.

In our issue of the 27th ult. is a letter of Messrs. Perken, Son, and Co., Ltd., which calls attention to a matter of some importance to purchasers of second-hand apparatus, and also raises a question as to whether anyone who has to make an important alteration in a piece of apparatus has the right to re-engrave the original maker's name upon it. In the case of Messrs. Perken, they were called upon to make an entirely new mount for a lens, and were requested to engrave the optician's name on the new mount. To this they demurred, and rightly so, we think. They were told by their customer that their scruples were absurd, and that he could get the work which they had declined done by another, "having business relations with all the best houses in London." If this thing were a recognised one in the trade—and we cannot imagine it is—it is easy to see that it would not be difficult for unscrupulous traders to create, as Messrs. Perken point out, two costly instruments out of one. This could, of course, be done by putting spurious glasses in the original mount, and the genuine ones in a spurious one. Many years ago a second or third-rate lens maker got himself into serious trouble by this procedure. It is tolerably well known now—more especially with the newer forms of lenses—that the mount is a very important part of the instrument. In some instances the most trifling alteration of the length of the tube, or in the separation of the glasses, may convert a most excellent instrument into quite a mediocre one. In any case, if a new mount is made for an instrument the name of the original maker of the instrument should not be put upon it. Many of the older portrait lenses were not supplied with central stops, and these could not be fitted without removing the makers' names. In these cases it was customary, when stops were afterwards fitted, to cut out the name and attach it, as a plate, on the side of the tube. We direct attention here to Messrs. Perken's letter to caution purchasers of second-hand apparatus against buying it without making sure that the whole of it was made by the makers whose names it may bear. When sold by a dealer of repute this may be relied upon—at least, so far as he is aware. In other cases the purchasers will do well to submit to the makers, who will always be pleased to verify it, or otherwise, without charge.

CLASHING OF EXHIBITION DATES.

OUR readers will have observed from an inspection of the list of forthcoming exhibitions, published week by week in another column, how frequently it occurs that one provincial photographic society has chosen a date for its annual exhibition clashing with the date of another or several other exhibitions. In some cases the dates are identical. In others, it will be found that they overlap in such a way that, although the actual shows are not open during the same period, yet the closing date of one exhibition is fixed so that it is impossible to get pictures returned to the exhibitors and repacked by them in time for delivery to another show. Whether this state of things is due to lack of observation on the part of the organisers, or whether no thought is given to the necessary support of the exhibition by the exhibitors, on whom, of course, the major part of the success of the venture depends, it is difficult to say. It is nevertheless obvious that an exhibition that is the only one of its kind open at a certain time is more likely to be a success and get more support in the way of exhibits than if two or three similar shows are competing with it during the same week. Yet the fact remains that season after season there is a recurrence of this exhibition clashing. Secretaries complain in many instances of the lack of support given their shows. The expected balance is found at the conclusion of the proceedings to be a deficit, and the usual excuse offered the members of the society at the annual general meeting is that the show received little support because there was a big show at A. and another at B.

Now, it seems to us that the remedy is entirely in the hands of the secretaries themselves. Let them combine or co-operate to produce a proper sequence of dates that do not clash, and the difficulties vanish. Of course, certain societies that are long-established organisations, holding their exhibitions at approximately the same date every year, would be bound to say: "We have always held our annual show on such and such a date; why should we alter it to assist other and younger societies?" There would be no need to alter them. Such fixed dates would stand, and form admirable starting-points for the formation of a sequence of other exhibitions by societies less advanced, but more anxious to assist in removal of the date-clashing nuisance. It appears that the hon. secretaries and councils of the older societies usually have a well-thought-out scheme for the production of a successful exhibition, and all particulars are announced well in advance. Others, on the contrary, wait until within sight of the exhibition season, and then decide on a date at the last moment to fit in with their other arrangements. Such undertakings hardly deserve success. We know of many an exhibition that has been rushed into without thought as to other shows held on the same date, and the result has been financial loss.

A move in the right direction was made by the Affiliation of Photographic Societies by publishing in the "Red Book" the approximate dates of future annual exhibitions of affiliated societies. Doubtless much more could be done in the matter by the executive of that organisation convening a meeting of the secretaries of exhibiting societies, and endeavouring to come to some agreement regarding a workable sequence of dates throughout the exhibition season, having due regard for the geographical proximity of one society to another. As the affiliation now includes practically all the more important English photographic societies, there is no doubt that others who hold exhibitions, but are not affiliated, would readily fall into line in the event of such an arrangement coming to pass. Needless to say, it would not be wise, if "new season's goods" are looked for, for any suburban

or provincial exhibition to be fixed during the run of the two big London annuals—the R.P.S. Exhibition and the Salon. The dates of these two are always about the same every autumn. If, however, an exhibition of the "rejects" is contemplated, the experiment might well be tried, and would probably meet with considerable success.

The fact remains that the exhibitor, be he that much-maligned but necessary individual the "pot-hunter," or otherwise, who desires to be represented by his best work at, say, two exhibitions which, under the present system, happen on the same date, and has only one set of pictures or lantern slides prepared, can only send to one of the shows, or else must produce a duplicate set, which is not always desirable or, in some cases, possible. This has been already observed, and, to some extent, obviated by certain groups of societies situated in the neighbourhood of each other. Here, the dates have been so arranged that they follow very closely. The pictures shown at one exhibition and entered for the next are packed and dispatched direct without further reference to the exhibitor, who, in the event of having entered for the complete series of, say, two, three, or four shows, and having dispatched his exhibits to the first one, has merely to pay the entry fees and cost of carriage between one exhibition and the next. This would appear to be the correct way of solving the difficulty, but, confined as it has been up to the present, to isolated groups of societies in certain districts, it is not far-reaching enough. What is wanted is the complete co-operation of all the suburban and provincial societies who hold annual exhibitions, and the fixing of a recognised order in which the exhibitions will run. It would be found impossible, however, owing to the number of exhibitions that occur annually, for the dates to be arranged otherwise than to allow the pictures of an exhibitor to be forwarded from exhibition to exhibition direct. The receiving society in each instance would pay all carriage, and, if necessary, retain the pictures until same was refunded by the exhibitor. These details could of course be arranged by a general committee.

This plan would at once save the photographer who exhibited much, a vast amount of labour in the way of repacking, although no doubt he would have occasional qualms as to the condition of his frames by the time they reached the last exhibition on the list. Provision might be made for this by the hon. secretary of each society, when acknowledging receipt of frames, stating briefly their condition. We do not, however, advise the adoption of the method employed by an exhibitor at an R.P.S. exhibition not many years ago, who, evidently having suffered much at the hands of exhibition packers, framed his exhibit, a work of important size, in solid iron.

Good scientific results have been obtained by the Daniels Expedition, which sailed for New Guinea about a year ago for the purpose of studying the manners and customs of the natives of some of the little-explored islands of the South Pacific Ocean. Major Daniels, the leader, who is returning home by way of Hong Kong and India, has devoted considerable attention to the diseases, especially cases of cancer, met with, and his notes on the subject should prove of much value. Other members of the expedition, including Dr. Seligmann, the newly-appointed pathologist of the Zoological Society, have already arrived in London with part of the collections made. These consist of an extensive series of objects of native workmanship and several cases of zoological specimens representing the fauna of the islands visited. The party were able to secure some excellent photographic records and cinematograph pictures, which will, no doubt, in due course be exhibited at one of the meetings of the Anthropological Institute.

A NEW LIGHT FOR PHOTOGRAPHY.

II.

Description of the Mercury Lamp.

THE lamp is constructed in the form of a glass tube, having platinum wires sealed in at each end. These wires lead the current to the electrodes. The tube is exhausted to a high degree on a vacuum pump and sealed off. This prevents any escape of the vapour which fills the tube, and also contributes to the efficiency of the lamp. The vacuum is much higher than in the case of the ordinary electric glow lamp. The tube is now usually made straight, but in some forms of the lamp is made V or U shape. It must in any case be of such shape as will permit of the ready flow of the mercury from one end of the tube to the other, as upon this depends the method of starting the lamp. One end of the tube is enlarged to a bulbous shape, and the mercury reposes in this when the tube is vertical.

Starting the Light.

The principle of starting the lamp is that when the current is switched on the mercury is disintegrated at the negative electrode, particles of mercury being thrown off and carrying the current to the positive electrode. Mercury vapour, however, under the conditions existing in the lamp, possesses a high initial resistance to the passage of the electric current. This resistance appears to reside between the negative electrode and the vapour, and must be broken down before the lamp can be put into operation. Of the various ways in which this may be accomplished Cooper-Hewitt has selected two. One consists in discharging a high potential spark from an induction coil, and the other is by tilting the tube so that the mercury runs down to the other electrode, carrying the current with it. The stream of mercury momentarily establishes a metallic connection between the electrodes and then breaks, usually at the bottom, where it ends in a spray. The lamp lights across the break, the luminous area rapidly extending up the tube as the stream of mercury falls away. Lamps over four feet long can be lit in this way, and for all purposes where practicable the tilting method of starting is recommended as being simpler and less expensive than the other. The lamp lights up almost instantaneously if the tilting is done steadily. With two lamps in series they are mounted on one frame and tilted simultaneously. When lamps are lighted independently each is furnished with a resistance which is automatically cut out when the lamp is started.

The Life of the Mercury Lamp.

The length of the tube, it may be mentioned, is proportionate to the voltage of the supply. On 200 volts the tubes are about four feet long, and although they seem likely to be very fragile, they can be handled with safety when in the framework in which they are mounted. When first installed the chief danger of spoiling a lamp is that the poles may be connected up in a reversed way, and even a momentary current through the reversed poles will spoil a lamp, rendering it unfit for any further use. It is necessary, therefore, to first carefully test with pole-finding paper or other means the polarity of the cables leading to the lamp before connecting the terminals. When once the lamp is installed there is little or no danger of any mishap, and the life of the lamp is theoretically infinite. No doubt it would be practically so if an absolutely perfect vacuum could be obtained. Lamps used over 2,000 hours show but a slight decrease in candle power. The best life of the average vapour lamp may be considered to be about 1,600 hours, whereas the best incandescent filament lamps cannot be run efficiently over 600 hours. Renewals of the tubes are furnished by the makers at a low rate.

Radiation of Heat.

A feature of the lamp is that there is comparatively very little heat from it. The temperature of the glass is slightly

higher than that of an incandescent lamp bulb. The radiant heat, however, is not so great, and consequently a vapour lamp heats up a room less than a cluster of incandescent lamps or an arc lamp. This absence of heat is of very great benefit in the use of the lamp for printing purposes.

Colour of the Light.

The most remarkable feature of the mercury vapour lamp is the colour of the light. Apparently it is a cold, brilliant white; but if white objects are illuminated it imparts a greenish tinge to them. Red becomes a purplish hue, tending towards black. Gold becomes a light greenish bronze. Greens, blues, and violet appear more natural. Flesh tints are ghastly, a white face being a sickly greenish hue, whilst any ruddy patches are a dark purple, as also are the lips. By some people the light has been likened to that produced by the monochromatic sodium light, but that is incorrect, for in the latter case all colour differences are abolished, and everything becomes black or yellow. With the mercury vapour lamp there is, however, plenty of colour, but it is not correct. Flowers and other brilliantly-coloured articles appear wonderfully coloured, but the colours are not their natural ones. As one writer has expressed it, "The light plays such pranks with colour that the colour sense seems to have gone crazy. One red thing will appear blue, another black."

The Spectrum of Mercury Vapour.

The cause of this eccentricity of colour is not far to seek if we examine the spectrum of the light. There is no red what ever; but there are two bright orange lines which are difficult to obtain photographically with an exposure sufficient for the other parts of the spectrum. No yellow is to be seen, but there is a yellow-green line which is not very actinic, then a brilliant green line, a broad dazzling blue-violet line, and two more broad bands up to the end of the visible spectrum.

I reproduce here one of a series of spectrum photographs of the light, and the superposed continuous spectrum of the arc light, with sodium introduced to give the D line will enable a comparison to be made:—

D

A. Spectrum of open arc showing D line at 11 mm.
B. Spectrum of Cooper-Hewitt mercury light.

Widening of Spectrum Lines.

It will be seen that the lines of the mercury vapour spectrum, especially towards the violet end, are very broad. This is a characteristic of the spectrum, as of most gases, especially when under high pressure, such as will be indirectly produced by the high temperature of incandescence. Lommel states that an increase in the density or the pressure of a radiating gas causes a broadening of the bright lines in its spectrum, and at the same time displaces them towards the red. When spectral

of gases widen out in this way it will generally be found that the most refrangible lines widen most easily, as will be seen to be the case in the mercury vapour spectrum. This widening of the lines renders it necessary to give very short exposures and maintain a narrow slit, or an almost continuous spectrum formed. The spectrum photographs were made with Tallent's diffraction camera, with quartz prism and lenses, and the image has been cut off at the violet end owing to the overlapping of

the spectra of the second order, otherwise a considerable extension into the ultra-violet would be shown.

Having now given the reader some idea of the properties of the mercury lamp, I am in the position to consider in the third and concluding article the practical questions connected with its uses in photography. Its employment in portraiture, its installation in the studio, and its applications to printing, copying, and enlarging, will be dealt with next week.

WILLIAM GAMBLE.

THE WEEK IN HISTORY.

Fox Talbot.

TO-MORROW (February 11) a hundred and five years will have elapsed since the birth of Fox Talbot. It may not be generally known that his tastes while still a boy at school ran in the direction of chemistry. In a letter to his mother written in 1812 he refers to an explosion of a fulminating powder which had taken place. "The powder she describes," he wrote, "must either have been hyper-oxymuriate of potash, or one of the metallic fulminating powders which are so dangerous as they can never be removed out of the vessel in which they are made without exploding, and most likely a small portion had got between the cork and the neck of the bottle, which could infallibly explode by the friction of opening it." "Infallibly explode" is not bad for a boy of twelve, and no wonder that Dr. Butler, the head master of Harrow, wrote that he was "really distressed at removing him at so early an age to the fifth form; but if his acquirements are beyond his years, how can I help it?" Practical chemistry was a forbidden subject at Harrow in those days, and the youthful Talbot was accustomed to prosecute his study of it in the top of a neighbouring blacksmith.

Although there is nothing in his photographic papers to indicate it, Fox Talbot was a close student of the physics and mathematics of his day, and he graduated at Cambridge as a self-wrangler when he was twenty-one, and ten years afterwards obtained the Fellowship of the Royal Society for his papers in these branches of science.

The Germs of Calotype.

As I mentioned in the notes which appeared on January 20, the specimens of what he called "photogenic drawings" exhibited for the first time on January 25, 1839, were the results of experiments made some years previously, and set aside for a time. Fox Talbot explained that the idea of "fixing shadow" first occurred to him during a tour in Italy in 1833. He was using the camera obscura as an aid to sketching, when he conceived the possibility of making a chemical process the work of the hand. In January of the following year he was in England again at work on the problem, and, as I have already recorded, he was rewarded in 1835 with results which may be legitimately described as permanent photography. That process was crude enough, but it was a complete process, and Fox Talbot perfected it until he obtained in "Calotype" a very efficient photographic method. Though collodion superseded it in the studios, it was used for many years afterwards by travellers.

The Labours of Talbot.

By the time my reader has taken the fifty-two doses of history which I propose administering to him in the course of these pages from the past, he should have a pretty good idea of the shares in the making of photography taken by Talbot and Herschel, Niépce and Daguerre, but at this point may sum up Talbot's work, and see what sort of total it amounts to. I am the more inclined to do this as this week there is a regrettable dearth of events, and had it not been for the dispositions of Nature which brought Talbot into the world on this particular day of the year, I should have had to adopt the anticipatory method of the boy who received proposals for the division of his apple with his friend by the comment, "There ain't going to be no core." However, to take a rapid glance over what Talbot did.

He was the first to publish a permanent photographic process. He maintained a continuity of work, and brought this first crude process to a considerable degree of perfection.

His photography was that of the negative and positive, and all subsequent developments have been on these lines.

He was the first to apply successfully a photographic process to the making of a printing surface.

The justice of these claims on behalf of Talbot will be apparent from the accounts of his work which will appear in "The Week in History" as their position in the year determines.

"The Pencil of Nature."

Among these contributions to the photographic art there is one which would be omitted were we to confine ourselves strictly to those to which a given day can be assigned. In the year 1844 Talbot issued through Messrs. Longman, Brown, Green, and Longman, of Paternoster Row, the first work illustrated by photography. It was entitled "The Pencil of Nature," and each number consisted of six "photogenic drawings." The issue, however, did not extend to more than five or six numbers, but in the following year twenty-three photographs were issued under the title of "Sun Pictures in Scotland." In an introduction to "The Pencil of Nature," Talbot narrates how the idea of fixing the natural images of the camera came to him on the shores of Lake Como. "Whether," he writes, "it had ever occurred to me before amid floating philosophic visions, I know not, though I rather think it must have done so, because on this occasion it struck me so forcibly. I was then a wanderer in classic Italy, and, of course, unable to commence an inquiry of so much difficulty; but, lest the thought should again escape me between that time and my return to England, I made a careful note of it in writing, and also of such experiments as I thought would be most likely to realise it, if it were possible."

Talbot's "Subchloride" Theory.

In this same introduction Talbot speculates on the cause of the fact discovered by himself that when less salt was used (i.e., as we now express it, when there was excess of silver nitrate) the paper possessed much greater sensitiveness. Talbot was sure of his facts, but his explanation of them reads very curiously in the present state of our knowledge:—

"A sheet of paper was moistened with a much weaker solution of salt than usual, and when dry it was washed with nitrate of silver. This paper, when exposed to sunshine, immediately manifested a far greater degree of sensitiveness than I had witnessed before, the whole of its surface turning black uniformly and rapidly, establishing at once and beyond all question the important fact that a lesser quantity of salt produced a greater effect. And as this circumstance was unexpected, it afforded a simple explanation of the cause why previous inquirers had missed this important result in their experiments on chloride of silver, namely, because they had always operated with wrong proportions of salt and silver, using plenty of salt in order to produce a perfect chloride, whereas what was required (it was now manifest) was, to have a deficiency of salt, in order to produce an imperfect chloride, or (perhaps it should be called) a subchloride of silver."

HISTORICUS.

POSTAL PHOTOGRAPHIC CLUBS.

THAT photographic societies have been of the utmost use in popularising photography and instructing the beginner every one will admit (writes C. C. Vevers in "Photographic Scraps"), but there exists among a certain section of devotees to the art a kind of bashfulness, a nervous dread of publicity, which renders them utterly incapable of asking questions, or submitting examples of their work for the criticism and advice of more expert photographers at the meetings of societies. It is with a view to encourage such latent talent as these workers may possess, and to assist others whose timidity prevents them from making their wants known in an open meeting, that most postal photographic clubs have been called into being.

Specialists' Clubs.

There is also another class of postal club for advanced workers who specialise in certain branches of photography, such, for instance, as architecture. Here the members can compare work and notes with other experts in their own department, and they can, if the circle covers a wide area, as it often does, see examples of their particular study from all parts of the Kingdom. In any society the number of photo-micrographers could probably be counted upon the fingers of one hand; few societies can boast of more than one or two members who devote special attention to this useful branch of scientific photography. How gladly would many avail themselves of the opportunity of seeing and criticising the work of others through the medium of a postal club!

"General" and "Special."

There are, then, two types of postal clubs—the "general," which admits photographic work of any description; and the "special," whose members submit one class of work only.

The "general" club may be taken to be one formed for the benefit of the amateur who tries everything or anything, and who is, perhaps, not markedly proficient in any department. It is a sort of "mutual help society," in which each one seeks to become more skilful by receiving and giving advice, and comparing the results of his efforts with those of his fellow members.

Organisation.

The general scheme of such a club is roughly as follows: Each member inserts a print or prints in the portfolio, or other protecting cover; as it reaches him, he criticises the other members' contributions, offering suggestions for their improvement according to his notions of art and photographic technics. For this purpose he is allowed to retain the portfolio for a limited time, and he then passes it on to the next member, who does likewise. And so it goes on until it has gone the round of the members, when it is started on its second circuit, each member removing the prints he previously inserted, and replacing them with others.

From twelve to twenty members are generally found a sufficient

number to form one circle or club, and the time each one is allowed to retain the portfolio is limited to from two to five days. Generally three days will be found to allow ample time for each member to insert his prints, criticise the others, read the notes, and so on.

Whole-plate is generally regarded as the maximum size of prints contributed, but, of course, this rule is open to modification according to circumstances. In order to keep the weight down as much as possible, there is also a rule generally made against the use of thick mounts, for if every member inserted three or four prints upon plate-sunk mounts, for instance, the carriage from one to another would become quite a costly affair. Stout paper mounts can be purchased in various tints to suit all classes of printing processes, and are very suitable for postal club purposes. They are cut to allow an effective margin round standard sizes of prints, those for half-plate size measuring about 10 by 8 inches, which can also be used for the few whole-plate prints that may, from time to time, be contributed. The portfolio should, therefore, be made to take this size, say, 11 by 9 inches.

It is desirable that the members should furnish the fullest information regarding the conditions under which the negative and print were made.

Criticisms.

Space for criticism must be provided also, and the best plan is to supply each member with a number of folded sheets of writing paper sufficiently large to enclose the mounted print. A writing paper known as "large post," which measures about 21 by 17 inches, when cut in half and folded, just makes a suitable sheet to contain a print mounted upon 10 by 8 inch paper. The front of this sheet should be reserved for member's name, title of subject, exposure, and other data, and the other three sides can be used for criticisms. Such a sheet keeps the print and mount clean, the prints can be stored in them after removal from the portfolio, and the sheets will often be found extremely useful for reference in the future.

Postal Club Activities.

A note book should accompany the portfolio on its journey for the insertion of items of interest, questions and answers, the exchange of prints, and other matters in connection with the club. Each round a discussion might be conducted upon some subject selected by the secretary, or suggested by a member. A list of dark rooms and lodgings at photographic resorts could also be made by the members from personal knowledge; and, in like manner, a useful list of "places to visit" and "what to take" could, in the course of time, be built up. Indeed, this note book would soon become as interesting and instructive a feature of the club as the portfolio itself.

An annual subscription of 2s. or 2s. 6d. will generally be found ample to cover all secretarial expenses, including the cost of portfolio, note books, printed covers for prints, etc.; indeed, I know some clubs which are worked on a subscription of a shilling a year.

MR. HENRY M. WARD, trade photographer, of Belgrave Avenue, Leicester, sends us his current list of prices for enlargements and printing. Sepia bromides, an effective form of the toned bromide, are a strong line of his, and in their special mountings of sea-green, brown, and deep cream produce an exceedingly rich appearance. The "Auró" enlargement, of rich brown colour, is another speciality which the firm lists, at very moderate prices, on paper and opal.

BROWN Tones on Lantern Slides.—Messrs. Burroughs, Wellcome are drawing attention to the use of the pyro soda developer in a particular way for the obtaining of golden brown tones on lantern plates. The following are the instructions issued by them:—In 2 oz. of water dissolve one "tabloid" pyro accelerator. Add 5 to 8 grains

of potassium bromide—the most convenient way of doing this being, of course, to use 5 to 8 "tabloid" products, each containing one grain of potassium bromide. Use lantern plates specially prepared for the production of warm tones, give them several times the normal exposure, and immerse them in this solution of accelerator and bromide for one or two minutes. Then pour the solution back into the measure, and in it dissolve one "tabloid" pyro developer. Pour back the mixture and develop in the usual way. The result is a beautiful golden brown tone; which looks exceedingly well in the lantern. Warm black tones are also obtainable with this developer by taking the normal developer as for negatives, but adding "tabloid" ammonium bromide according to the exposure and to the warmth of the black desired.

FOCAL-PLANE DISTORTION IN AUTOMOBILE PHOTOGRAPHY.

[A Portion of a Paper in "The Motor-car."]

THE author, in undertaking an analysis of the conditions under which the distortion of motor-car wheels takes place when they are photographed at a high speed, assumes a very narrow slit—of one-eighth of an inch—and a rate of movement of the shutter equal to a passage over a 5-in. plate in 1-30th of a second. On this basis the local or relative speed becomes 1-1,200th of a second, and this figure is one which Mr. Claudy assumes to be attained in practical work.

Exposure Conditions.

The next factor to consider is the relation between the distance between automobile and lens, and lens and plate, for, this known, and the speed of the automobile known, a simple calculation in proportion gives the speed of the image of the moving automobile across the sensitive plate. Suppose, for the sake of argument, that the distance from the lens to the plate is 1 ft., and from the lens to the passing car is 10 ft. Suppose that the speed of the car is greater than 88 ft. a second (mile a minute) and is 100 ft. a second. Then, to find the speed of the image on the plate in feet per second, we solve the equation:—

10 (feet from object): 1 (foot between lens and plate): 100 (feet per second of car in road): X (feet per second of image of car on plate).

10:1::100:10; therefore, the automobile crosses the plate at the rate of 10 ft. per second, or 1 ft. in 1-10th of a second, or 5 in. (the size of our theoretical plate) in 1-24th of a second. Now, if the speed of the slit of the shutter were 1-24th of a second, a point would get its picture taken at the corner of the plate when the slit started to move; some point in the automobile just above this would get its picture taken further sideways, and the topmost point of the automobile, probably the driver's cap, would get its picture taken at the other corner of the plate, since the motion of the slit and the motion of the moving image is performed at equal speeds. Naturally this would give a very distorted effect, the whole automobile appearing to lean in the direction in which it is going. As a matter of fact, the speed of the slit is from 1-30th to 1-50th of a second, and few automobiles go 100 ft. a second, or are taken with so long a focus lens so close as 10 ft. Therefore, the paths I have indicated more nearly represent the real state of affairs, and the path with least inclination is the most correct, as the car seldom, if ever, fills the whole plate, so that the space occupied by the machine is not more than $2\frac{1}{2}$ in., which, of course, cuts the distortion in half.

Shutter Speeds.

I am sure to be questioned here by those not familiar with focal-plane shutters as to the correctness of my statements regarding the speed at which they work. It is perfectly true that the picture as a whole receives an exposure which amounts to only 1-1,200th of a second, but it is equally true that the small aperture in the curtain seldom, if ever, passes over the 5 in. of the plate in faster time than 1-50th of a second, about fifteen miles an hour. And this, when you come to think of it, is a remarkable thing in itself—that any mechanism, small and light enough to be carried in the hand, can jerk, from a state of rest, a curtain, rush it suddenly at fifteen miles per hour for 5 in., and then as suddenly check its motion, and all without breaking a spring or injuring the mechanism! If the matter is still

not quite clear, re-read what I said above regarding the size of the aperture of curtain and the speed of the slit.

Another factor in this matter is that, by a law of optics, the image on the sensitive surface is upside down. By a law of the camera maker, curtain shutters operate from top to bottom. It is plainly to be seen, therefore, that the bottom of the wheels and the bottom of the automobiles get their pictures taken first, then the middle, which in the meantime has moved, and finally the top, which has moved still more.

Wheel Movement.

I now come to the last factor in this matter, and one which is really most important, as it is most interesting and seemingly paradoxical. The distortion is always greater in the wheels than anywhere else, and also always greater at the tops of the wheels. This would seem but natural according to the foregoing explanation, were the distortion equal all over the car, but, on the other hand, that of the tops of the wheels far exceeds that anywhere else. This is because the upper parts of the wheels travel several hundreds per cent. faster than the lower parts, while all the rest of the automobile moves at a uniform speed.

Obviously, the upper spokes of a wheel revolving on the ground travel, with reference to any fixed point, at a much greater rate than those near the ground. Of course, were the wheel revolving in the air, or considered with reference to its hub only, all parts would have to be considered as moving at the same speed.

However, we have to do with a fixed point, the lens of the camera. The slit of the shutter secures the impression of the lower part of the wheel first. As it slides across the plate and the upper part is taken, the speed of the image rapidly increases as it approaches the top of the wheel. The motion is thus shown more plainly at the top of the wheel than anywhere else, and any given point has a chance to slide a little further on the plate than those below it, which gives to the top of the wheel a blurred look as well as a distinct forward inclination.

An Example.

It may be interesting to state that when the upper spoke is absolutely perpendicular its extremity is going at double the speed of the car—120 miles per hour, if the car be making sixty; 200 ft. per second if the car be making one hundred. This also is a very simple calculation. The spoke from the free end to the ground end is to be considered as a lever. The ground end is the fulcrum, the hub the point of power application. As the upper point of the spoke is twice the distance from the fulcrum that the hub is, any movement of the hub must be twice amplified at the upper part of the spoke. Consequently, if the hub (the car) be making sixty miles per hour, the upper point of the spoke must be making double that, or 120 miles per hour. Of course, this condition of affairs obtains for only a theoretical instant. The fulcrum is not fixed, but moving, and the upright spoke of one instant becomes the horizontal spoke of the next.

Still, in dealing with pictures, we have to do with minute fractions of a second, and the doubled speed of the top of the periphery of the wheel is an important factor in the egg-shaped distortion which I have tried to explain in as simple a way as possible.

C. H. CLAUDY.

THE Birmingham Exhibition.—We would remind those of our readers who are sending to the exhibition of the Birmingham Photographic Society that but one day remains before the entries must be with the secretary. They should reach Mr. Lewis Lloyd, at Norwich Union Chambers, Congress Street, Birmingham, not later than tomorrow, Saturday.

MEMBERS of societies, clubs, etc., may be interested to learn that the Official Information Department for the Isle of Man (established by the Manx Government) is now lending, free of charge, a series of lantern slides (with descriptive reading) illustrative of a tour throughout that picturesque island. Particulars may be obtained from the Secretary, 2, Coronation Chambers, Douglas, Isle of Man.

Photo-Mechanical Notes.

The Effect on Zinc Plates of Enamelling the Image.

ZINC, being a much cheaper metal than copper, and, to a certain extent, more quickly etched, is still used for half-tone plates. Some years ago the albumen process was practically the only printing method for process blocks, and with this mode of printing, zinc answered all purposes. When the enamel process was introduced, however, it was soon found that the zinc plates did not stand the wear and tear of the printing machine so well, the effect of enamelling, or burning-

Fig. 1.—Photo-micrograph of Fractured Edge of Zinc Plate.

Fig. 2.—Photo-micrograph of Fractured Edge of Zinc Plate "Perished" by Heat.

in, the image being to soften the metal and render it more brittle.

The cause of this softening of the zinc plate is, of course, the intense heat required to effect the enamelling of the fish glue or gum arabic used in printing. With albumen printing comparatively little heat is required to "set" the resin and ink. "Perished" zinc is the term applied by the trade to this burnt metal, and in consequence of the inability of the cheaper material to stand the enamelling process, it was abandoned by

many firms for half-tone work; copper or brass, which are practically unaffected by burning-in, being substituted.

The effect of enamelling is to destroy the grain and structure of the rolled metal, and the zinc becomes what is usually termed "crystalline" in structure. The change that has taken place in the metal can easily be detected by bending a strip of perished zinc close to the ear. The rending of the metal can be heard distinctly. When a strip of zinc that has not been heated is bent, no sound is heard.

The accompanying photographs demonstrate the change that takes place in the metal by enamelling. Fig. 1 shows the fractured edge of a piece of rolled zinc before heating. It will be seen that the fracture is of an uneven nature owing to the toughness of the prepared metal, and the grain is of a close texture.

In Fig. 2 the fracture point of a piece of "perished" zinc is reproduced. The break is of an even nature as the metal has lost its toughness, and the grain is of a very different structure from that of Fig. 1.

J. I. Pree.

The paper by Mr. J. W. Lovibond before the Society of Chemical Industry, on Monday last, the 6th inst., was a disappointment to anybody who expected to gather any information on the fading of inks used in trichromatic printing. The author did little more than refer to the method of exposure of the inks to light and exhibit the curves of fading obtained by measurements in the tintometer. The inks were exposed to a north and south light, under the normal conditions of atmosphere found in a furnished house. They were also exposed under a bell jar containing a wet sponge, and it was found that the presence of moisture notably affected some of the results. The total time over which the exposures extended was only five weeks, and it was suggested that the tintometer, by measuring very minute colour differences, was able to provide a useful means of comparing paints and colours in regard to permanency. Unfortunately no details were given of the chemical composition of the inks examined, nor was any statement made as to their commercial origin. Possibly when the paper appears in full in the society's journal it may be possible to extract some of the practical facts which it doubtless contains.

New Book.

"Der Gummidruck in Natürlichen Farben," by C. L. Armin. Published by "Gut Licht." Vienna xviii 2.

This pamphlet is a reprint from our contemporary "Gut Licht," and according to its sub-title, it is "the first description of the trichromatic positive process." The exact date of its publication is not given, but from internal evidence we gather that it must have been issued in the last month or two, and having ignored or being ignorant of all that has been done in the matter by Ducos du Hauron, Vidal, Ives, Sanger Shepherd, Lumière, Miethe, and others, the author proceeds to give us his three-colour printing process, which resolves itself into a first printing with a bright cadmium lake, a second with Florentine lake (red), a third with Prussian blue (thin), a fourth with deep Prussian blue, a fifth with madder lake, and a sixth with yellow lake or saffron. Three colours, but six printings and all in gum. There are easier and more reliable methods we think.

WILLIAM THEODORE SANDERS, photographer, of Bournemouth, was committed for trial last week on the charge of stealing a camera value £16, the property of James Low Warren, of the "Bournemouth Graphic."

Exhibitions.

BLAIRGOWRIE AND DISTRICT.

THE exhibition of the Blairgowrie and District Photographic Association opened on Monday last, the 6th inst., and will close to-morrow, Saturday. 450 entries are contributed. The Public Hall, where the exhibition is held, is eminently suited for the purpose of a photographic exhibition, being entirely lit from the roof; the walls have been hung with a neutral tinted canvas, which displays the pictures to advantage, while the pictures themselves have been carefully arranged on the walls under the superintendence of Mr. Ewan Geddes, whose valuable services in this direction can hardly be over-estimated.

In the Champion class there is a galaxy of well-known pictures, and the local photographers are revelling in the making the acquaintance of pictures previously known through reproductions only. The judges awarded the plaque to Dr. Boon's "Convalescent," in which the beautiful rendering of tone and arrangement of lines appealed to all; meritorious work—outstanding work, in fact—is shown in this class by the leading exhibitors, including Dr. Grindrod, S. G. Kimber, E. Seymour, Jas. Patrick, W. Clayden, J. C. Warburg, Miss Warburg, A. H. Allan, A. W. Hill, Graystone Bird, A. H. Avery, John Spark, Fred Judge, and J. C. Robertson, etc., etc. Dr. Boon's picture is also awarded the silver plaque for the best picture in the exhibition, and he annexes another plaque with his street scene in the landscape class. In this class a plaque is also awarded to A. C. Milne, Brechin, for "A Highland Descent," a strong and realistic rendering of a highland stream in spate, the overwhelming onrush of the water being graphically depicted. This class is a large one, and contains a plethora of good things, such as Dr. Grindrod's "Crossing the Ford" and "Hauling Timber," J. C. Warburg's "Shadow of the Cliffs," "The Adur Bridge," and "The Gothenburg Boat"; J. B. Johnstone's "A Lonely Shore," "A Cherry Orchard in Spring," and "The Orchard Way," by Agnes B. Warburg, "Toilers of the Field," by Dan Dunlop, "Here a Sheer Hulk," by J. E. Latham; entries are also included from P. B. Clarke, Japan, Wilfred C. de Tain Bly, K.C.M.O., Constantinople, Arthur J. Fuller, and J. G. Rose, Capetown.

In Portraiture and Genre, the judges have only awarded one plaque, viz., to "Sir Edward Elgar," by Dr. Grindrod. A second study by Dr. Grindrod is "A Cornish Fisherman," and is essentially strong portraiture, the hand of Time has drawn the wrinkles of experience on the tanned face of the veteran salt, and the photographer has shown up these in all their gnarled picturesqueness. Although only one plaque has been awarded it must not be thought that the class is weak, the reverse is the case. Mrs. Baird, Broughton Ferry, has a realistic study of "Gipsy Life," for which she is awarded the silver medal given by the "Amateur Photographer" for the best picture in the exhibition by a lady. Peter G. Terras has several good studies of "Gipsy Girl"; "The Old Fiddler," by F. W. Urquhart, Dingwall, is a telling picture; Miss Warburg has two characteristic entries; "The Forum—Julius Cæsar's," by Arthur Payne, Gateshead, is unique in its way; John Smith, Dundee, shows one of his "slum" pictures, "A Youthful Outler," while A. H. Allan, Edinburgh, ventures one portrayal of the male persuasion in his "Auld Rab"; two pictures from H. A. Reed, Gibraltar, convey the warmth of the sunny south; John C. Warburg shows two pictures stamped with his own individuality; amongst others who show good work, of which space forbids detailed notice, are John Terras, John Smith, Hastings, E. S. Baker, Birmingham, Graystone Bird, Bath, W. R. Kay, Southampton, T. Ritchie, Wishaw, Dan Dunlop, Motherwell, John Spark, Perth, Mrs. Clarke, Yokohama, John B. Anderson, Belfast, and Miss May Donaldson.

In the "Any Subject" class a plaque is awarded to "Paeonies," by D. W. Kyle, Glasgow, a fine rendering of these flowers. In this

class John C. Warburg's "Fairy Clocks," printed in a daring shade of green, attracted much attention, and secured some favourable comment; E. Seymour, Watford, had some charming fruit and flower studies; Miss Warburg showed her unique conception of "The Marble Arch"; Dan Dunlop was represented by architecture and fruit, W. R. Kay, Southampton, John B. Anderson, Belfast, and others by architecture; Robert Dykes, Edinburgh, showed a clever "night" picture.

Lantern slides was a strong class, and here the judges awarded three plaques, viz., "White Currants," by E. Seymour, Watford, noticeable for the brilliant transparency of the fruit, "Mother's Help," by Rev. H. W. Dick, Manchester, in which the "help" was delightful, and "Gala Night, Scarborough," by Graystone Bird, Bath, a representation of fireworks with telling reflections in the water in foreground; the mention of a few names will indicate the high quality of the work:—F. G. Tryhorn, London, Godfrey Bingley, Leeds, W. S. Crockett, Glasgow, Rev. E. T. Clark, Gloucester, Geo. A. Booth, Preston, John Stabb, Torquay, W. R. Kay, Southampton, and H. Wormleighton.

In the Lecturette Class the result had not been received at time of writing.

The class confined to associates of the Scottish Photographic Federation was one of the strongest in the exhibition. Plaques were awarded to Jas. C. Robertson, Brechin, "The Picture Book," and it is noticeable that the judges preferred it to his R.P.S. success, "The Minister's Man," which was competing in the same class; Jas. D. Ross, Brechin, "Practising," and G. D. Macdougald, Dundee, "Bridge and Canal at Bruges," a beautiful little bit-gum; Messrs. Robertson and Macdougald's exhibits, to which were awarded plaques, were reproduced in the Scottish Salon catalogue. The above winners showed many other good works besides the plaqued pictures, and to individualise the works deserving notice would monopolise over-much space.

The plaque for best exhibit (six pictures) by a Federated Society was won by the Brechin Photographic Society.

In the three members' classes plaques are awarded to D. G. Monein, "At the Muirton," Jas. M. Donaldson, "The Last Rose of Summer," J. B. Young, "Birds of a Feather," Lake Falconer, jun., "The Crypt, Glamis Castle."

The judges were Messrs. J. Craig, Annan, Glasgow; Arch. Cochrane, Barrhead, and Wm. Crooke, Edinburgh; and for Lecturettes: Mr. Alex. Keighley, Keighley, Yorks.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE pictures sent in to the Society's annual competition are now on view in the Club Rooms, 9, Eberle Street, Liverpool, and, on the whole, the show is an excellent one. In Class A, which is known as the Champion class (to which the winning prints in the other classes are added previous to its being judged) Mr. C. F. Stuart easily takes first place with his set, of which "The Light in the West" is by far the best, being in all-round merit, considerably above his other two; and Mr. Stuart may be said to have fairly gained the gold medal and "Appleby" trophy. After this set comes Mr. J. D. Johnston's, the best of which is "Urgent Business," a winter scene on the River Mersey. The work is somewhat ordinary, notwithstanding excellent technique, and the worker may be congratulated upon being awarded an extra silver medal. Mr. C. J. Meyer's set of Continental figure studies is to be commended, while Mr. Canevali's work is mostly spoiled by theatrical and false lighting, and he would be well advised to leave more to nature and less to "faking." His third print, however (No. 6 in the catalogue), is a soft and effectively-lighted picture. Mr. Corney Wilson's "Windy March" is a nice breezy subject. In Class B, Dr. Holland gains the silver medal with three prints, the best of which is "The End of an Italian Valley." Mr. Selkirk's "Blowing Squally" is an excellent picture which the title fits admirably. His "So Smiled the Day" is also a fine subject.

but slightly marred by false light in the sky. In Class C a silver medal is awarded to Lieut.-Colonel Pilkington for an excellent set of architectural subjects. This medal, however, should have gone to Mr. J. D. Johnston for his charming set of Continental pictures, which are mounted, lettered, and framed in great taste—perhaps the best presented set in the exhibition. He was, however, debarred by the rules of the competition. Mr. W. A. Taylor carries off the other silver medal in the class. In Class D. Mr. H. R. Heap gains the bronze medal with a very creditable set, and as this is a beginner's class, he should be encouraged by his success. In Class E. (also a beginner's class) Mr. H. H. James gains the bronze medal for a good architectural set. The excursion prize is well earned by Mr. Canevali, whose figure studies are excellent. The second prize goes to Dr. J. W. Ellis, who also has a fine set. The president's prize for the best portrait of a member taken by a member in the club studio, is well earned by Mr. John Smith, for an excellent portrait of Dr. Holland, the work in this class being of very high quality. Mr. Carruther's portraits are spoiled by execrable mounting and framing. The premier prize for lantern slides is taken by Mr. H. Holt, who gains the gold medal in Class F, in which class Dr. Ellis also has an excellent set, the best of which is probably Canterbury Crypt. In Class G (lantern slides) the silver medal goes to Mr. J. W. M. Richardson, and in Class H. (lantern slides) the bronze medals go to Colonel Pilkington and Mr. Victor Prince.

GLASGOW AMATEUR PHOTOGRAPHIC ASSOCIATION.

THE annual exhibition, under the auspices of the Glasgow and West of Scotland Amateur Photographic Association, held in the Association Rooms, 180, West Regent Street, compares very well in all respects with those of previous year. The average merit of the work exhibited is as high as ever, and reflects the greatest credit upon amateur photographers in Glasgow and the West of Scotland. The entries show, if anything, a slight increase over those of last year. As usual, the exhibition is divided into five sections, the first, including landscape, seascape, architecture, flowers, etc. (half-plate size or smaller); the second similar subjects, the sizes of which are above half-plate; the third, portraiture, figure studies, animals, etc.; the fourth, pictures taken at outdoor meetings in 1904; and the fifth, lantern slides. The principal prize-winners are well known at these exhibitions, and in many instances the outstanding excellence of their work would have justified the judges in awarding them extra prizes if it had been within their power to do so. The awards are, however, confined to one for each competitor in any one section, and consist of bronze plaques of equal value. The judges were Messrs. Auld and Forbes, of Edinburgh, and W. Ralston, Glasgow. Their awards are as follow:—

Class A.—W. B. Summers, "A Moorland Path" (97); Robert Burnie, "White Currants" (113); Thomas Walker, "A Winter Landscape" (127).

Class B.—John Hepburn, "Blackadder Crypt, Glasgow Cathedral" (3); Thomas W. Robertson, "A Winter Landscape" (13); Dr. Richmond, "How Calm and Beautiful" (28); Robert Burnie, "Cobham Mill" (65).

Class C.—John Hepburn, "When Ance Life's Day" (146); J. R. Forrest, "The Fisherman's Siesta" (157).

Class D.—William M'Phun, "Homeward Bound" (188).

Class E.—Robert Burnie, six lantern slides, "Kitten Studies" (217); James Baillie, six lantern slides (196).

CARDIFF WINDSOR.

THE Cardiff Windsor Amateur Photographic Society deserve compliment upon having scored a success with their first exhibition, which opened at the Town Hall last week. A large number of well-known workers have entered for competition, and it is especially pleasing to record that members of the society have gained many of the awards which were made by the Rev. F. C. Lambert. Among the chief local

successes are Mr. Fred Cox, the president of the society; Mr. A. W. Woodward, the hon. secretary; and Mr. Yonker, of Barry Dock. Mr. F. H. Brown, another member, secured the silver cup presented by Mr. Harold Lloyd for the best marine study with representation of a breaking wave.

WOODFORD PHOTOGRAPHIC SOCIETY.

THE eleventh annual exhibition of the above society was opened at the Wilfrid Lawson Hall on February 3. The prints shown number 155, and are by 38 members of the society, giving an average of 4.1. Amongst the exhibitors are Messrs. E. Marriage, F.R.P.S., H. Wilmer, F.R.P.S., H. T. Malby, F.R.P.S., E. H. Carpenter, A. Ziegele, F. G. Emler, E. H. R. Hillsworth, F. G. Newmarch, E. C. Winney, W. F. L. Wastell, G. H. Grimsell, W. C. Smith, A. G. Brine, W. W. Donaldson, J. J. Blundell, D. Kemsley, F. E. Holmes, J. Sparling, W. Orme, E. T. Wood, R. A. Malby, C. A. E. Chandler, T. W. Pallett, T. J. Tee, C. F. Gould, E. B. Cook, E. C. Simmons, A. J. Kirby, G. S. Fish, H. W. Coke, F. E. Holmes, G. E. Anderton, S. Tymms, J. Irwin Packington, T. W. Pallett, A. Heim, T. F. Harding, J. P. W. Goodwin, and A. Horsley Hinton.

FORTHCOMING EXHIBITIONS.

February 6-11.—Blairgowrie and District Photographic Association. Hon. Secretary, Wm. D. M. Falconer, James Street Cottage, Blairgowrie.

February 14-15.—Royal Albert Institute, Windsor. Hon. Secretary, Mr. Jas. W. Gooch, 9, High Street, Windsor.

February 15-March 15.—International Exhibition Artistic Photographs, Vienna. Hon. Secretary, Dr. Reiniger, Camera Club. Largerplatz No. 3, Vienna III., 3.

February 16-18.—Norwich and District Photographic Society. Hon. Secretary, E. Peake, Rydal House, Earham Road, Norwich.

February 21-March 7.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

February 24-March 4.—Northampton Photographic Society. Entries close February 14; for pictures, February 17. Hon. Secretary, E. J. Felce, 85, Adam's Avenue, Northampton.

February 25-March 4.—Birmingham Photographic Society. Hon. Secretary, Lewis Lloyd, Norwich Union Chambers, Congress Street, Birmingham.

February 25-March 11.—Edinburgh Photographic Society. Entries close February 11; for pictures, February 15. Hon. Secretary, J. S. McCulloch, 3A, North Saint David Street, Edinburgh.

March 4-11.—South London Photographic Society. Hon. Secretary, H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 7-14.—Brentford Photographic Society. Hon. Secretary, F. H. Read, Ferndale, Clifden Road, Brentford.

March 16-30.—International Photographic Exhibition, Earl's Court. The Organising Managers, 119-125, Finsbury Pavement, London, E.C.

March 20-25.—The Cripplegate Photographic Society. Hon. Secretary, John B. Parnham.

March 27-April 1.—Leicester and Leicestershire Photographic Society. Entries close on March 20, 1905. Secretary, R. Warden Harvey, Oriental Cafe, Market Place, Leicester.

April.—International Exhibition, Genoa. Sec. Gen., Piazza Fontane Marose 18, Genoa.

April 3-15.—Photographic Society of Ireland. Hon. Secretary, R. Benson, 35, Molesworth Street, Dublin.

April 7-May 8.—International Artistic Exhibition, Berlin. Director, Herr Franz Goerke, Maassenstrasse 32, Berlin, W.

May 1-31.—International Exhibition of Photographic Picture Postcards, concurrently with the 10th Salon. M. le Secrétaire Général du Photo Club de Paris, 44, Rue des Mathurins, Paris.

May 10 to June 19.—Salon of the Photo Club de Paris. Entries close March 1, and pictures must arrive by April 10. Secretary, Paul Bourgeois, 44, Rue des Mathurins, Paris.

June.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

March 31.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Limited, Ilford, E.

September.—Kodak. £400 in prizes for results on Kodak products. Kodak, Ltd., 57-61, Clerkenwell Road, London, E.C.

New Materials.

The "Wellington" Etching Plate and the "Wellington" Lantern Plate. Made by Wellington and Ward, Elstree, Herts.

We have submitted the sample of the etching plate to some practical tests, and find them clean-working and capable of giving a great amount of light in development, especially if hydroquinone be used. They are very slow, being almost exactly the same speed as a sample of wet collodion, against which we tested them, and of almost equally steep gradation. They show very little tendency to halation, much less than some other process plates. Their good qualities make them very suitable for line work. For half-tone work, on the other hand, their slowness is a drawback, and we find that (again comparing with a wet plate), while it is easy to get as good a dot in the shadows and middle tones of the negative, the high-light dots have the familiar spreading action found in all dry plates we have so far tried for screen negatives. Their sensitiveness, as shown by a test on the spectrum of the arc electric light, is at a maximum in the ultra-violet at about wave length, 3,800, and does not extend beyond the violet.

The lantern plate is suitable for both cold and warm tones, and we note that the makers recommend hydroquinone and caustic potash for the black tones and pyro-ammonia for the warmer colours. This choice of developers in our experience is as good as any, and by increasing the bromide in the pyro-developer we were successful in obtaining some pleasing brown and sepia tones.

The prices of the "Etching" and "Lantern" plates are 1s. per dozen in quarter-plate and $3\frac{1}{4} \times 3\frac{1}{4}$ sizes respectively.

The "Merito" Lantern-Slide Carrier. Made by W. L. Parkinson, Limited, 62, Dale Street, Liverpool.

As single lanterns are now so extensively used, on account of their portability for lantern exhibitions, a slide changer or carrier to give a dissolving effect and at the same time be certain in its action, is a thing to be much desired amongst lanternists. The "Merito" lantern carrier is well made and finished in polished mahogany, is reasonable in price, and fitted with a brass feeding and withdrawing frame, consisting of two rails or bars, leaving an open space between, whereby dissolving effects are obtained. At the end of the frame

a withdrawing hook comes in operation to remove one slide for the next to take its place, and whatever the thickness of the slide may be it is brought automatically into correct register. The feeding and withdrawing of the slides is worked from one side, dispensing with the necessity of any assistance to the operator. The feeding frame carries the slides in on the front side of the brass frame, i.e., the side nearest the lens. After the first slide is focussed, the second slide is carried in with the frame, pressing the lever hook out of action going in, and after the frame is pushed as far as it will go, the lever spring is released to bring the hook into action, and then withdrawn by the round end of the frame.

A number of newly-designed frames are now being issued by Messrs. Epstein, 33, Broad Street, Bristol, and our mention of the fact should induce photographers to investigate the selection which is offered them. The 20 x 16 antique brown oak is a carved and ornamental frame which we would signalise as extremely handsome in appearance. Messrs. Epstein, who have a new descriptive list ready for despatch, announce that they make a practice of making any size or design to order.

Two new series of Cooke lenses are being placed on the market by Messrs. Taylor, Taylor, and Hobson, Stoughton Street Works, Leicester. Of the same triplet type of construction as the Series III. and V. Cooke lenses, the new issues are designed to work at the large apertures of f/5.6 and f/4.5. Those of the former intensity, known as Series IV., are made in focal lengths of 6, 8, 11, and 13 inches. The f/4.5, Series II., in the three latter sizes only. The lenses are advanced for high-speed photography, for portraiture, and for photography under poor conditions of lighting. A further review of them will appear as soon as we have examined the actual instruments. Meanwhile an illustrated descriptive circular is obtainable from Messrs. Taylor, Taylor, and Hobson.

A vivid glazed showcard has been prepared by Messrs. A. E. Staley and Co., 19, Thavies Inn, Holborn Circus, London, E.C., in advertisement of the "Geka" series of chemical products. It will be sent post free to any one interested in the goods.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

ORNAMENTAL BORDER NEGATIVES.—No. 1,286. "Improvements relating to negatives for the photographic reproduction of ornamental borders or of composite designs or pictures and inscriptions on sensitised surfaces." Hugo Kuntzen, 37, Essex Street, Strand, London. (Richard Hoh and Co., Saxony.)

COATING AND PREPARING MEDIA.—No. 1,290. "Improvements in and relating to the coating or preparation of media for photographic purposes." James Harris Paul Gillard and Henry Hearn Molyneux, 7, Southampton Buildings, Chancery Lane, London.

LENSES.—No. 1,594. "An improvement in lenses."

LENSES.—No. 1,595. "An improvement in lenses."

FORMING IMAGES.—No. 1,596. "An improvement in a process of forming images." Ulrich Nehring, 19, Holborn Viaduct, London. (Date applied for under Patents Act, 1901, February 15, 1904, being date of application in United States.)

STEREOSCOPE.—No. 1,665. "Improvements in stereoscopes." Douglas William Hart, 23, Southampton Buildings, London.

RISING FRONT.—No. 1,708. "A simple rising front for hand cameras." Robert Jackson, 99, Hart Street, Moss Side, Manchester.

PHOTOGRAPHIC SHUTTERS.—No. 1,740. "Improvements in or relating to photographic shutters." Wilhelm Kenngott, 111, Hatton Garden, London.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

IMPROVED METHOD AND APPARATUS FOR THE PRODUCTION OF COLOURED PHOTOGRAPHS.—No. 1,008, 1904. "The inventor claims the method for the production of photographs in natural

colours without the aid of coloured filters, consisting in splitting up into a spectrum a beam of composite rays by the use of colourless, transparent means, separating such parts of the spectrum as desired, and collecting homogeneous rays into beams of complementary colours, which are caused to act simultaneously on suitably arranged sensitised plates. For executing the method described above a photographic camera in which the light-rays pass through a system of lenses (primary objective) in the front part of the camera, through a plurality of secondary lens-systems arranged in front of an equal number of sensitised plates, and through a system of colourless prisms arranged in the central part of the camera, between the said primary objective and the said secondary lens-systems, one prism or set of prisms serving to split up the beam of rays into a spectrum, sections of which are taken up by separate prisms-systems, corrected and collected to form a plurality of one coloured beams of rays. In the camera described above the adjustable arrangement of the device for collecting the separate parts of the spectrum, for the purpose of so regulating the relations of the said parts that the latter are adjusted for uniform times of exposure." Charles Julius Drac, 21-23, Mariensztadt, Warsaw.

FOLDING STAND.—No. 5,680, 1904. "A folding stand for photographic cameras, surveying apparatus, and the like, capable of being used as a walking stick and characterised by being formed of legs of light material, in which other legs slide up and down, the latter having a metal case and being held in any suitable position by a spring controlled catch, which at the same time prevents side turning, substantially as herein described and set forth. A folding stand as described above, which is held in folded position by means of a ring attached to a ferrule on one of the legs, substantially as herein described and set forth." Johann Becker, 46, Westbahnstrasse, 11te St., Vienna.

DISSOLVING SLIDE CARRIERS.—No. 22,283, 1904. "An improvement in lantern slide carrier operating mechanisms, namely, a mechanism comprising a head part, and upper and lower horizontal members, carried from same, forming a space between the same and the head plate, so that the mechanism does not interfere with or lie across the plate being illuminated or projected when moved into and out of position; and one or each of such horizontal members having connected with it or them a catch, adapted to engage with the slide to be removed when the mechanism is moved out, and withdraw the plate; the said upper and lower horizontal members being adapted to slide in the carrier frame; for the purposes specified. A lantern slide carrier operating mechanism, adopted to feed in a fresh slide, and withdraw the used slide, having connected with it a spring or springs adapted to hold the slide being illuminated or projected against the carrier frame while a fresh plate is being introduced; substantially as set forth." William Lawrence Parkinson, 3A, Imperial Chambers, 62, Dale Street, Liverpool.

STABLE HYDROSULPHITES.—No. 6,216, 1904. "The hydrosulphite is prepared in combination with a ketone such as acetone or methyl-ethylketone, in the presence of alkalis. It is stated that the stability of the acetone-hydrosulphite preparations thus obtained is such that the reducing power of the solution is only a little diminished after several weeks and at a temperature of 50 deg. C. The solution may be evaporated in a vacuum at a low temperature to obtain the acetone-hydrosulphite preparation in the solid state in which it is very stable." Abel and Imray, Southampton Buildings, London, E.C., for Meister Lucius and Brünig, Höchst-on-Maine, Germany.

THE death is announced of Dr. A. V. Griffiths, of Fenton, and a prominent member of the Fenton Amateur Photographic Society.

THE ROYAL PHOTOGRAPHIC SOCIETY COUNCIL ELECTION.

THE following is a copy of the balloting paper:

President, *Major-General J. Waterhouse, I.A.; vice-presidents (erase not fewer than five names), *Sir W. de W. Abney, K.C.B., F.R.S., *the Right Honourable the Earl of Crawford, K.T., F.R.S., *Douglas English, B.A., *F. Hollyer, Dr. G. Lindsay Johnson, M.A., M.D., Chapman Jones, F.I.C., F.C.S., *J. C. S. Mummery, *E. Sanger Shepherd, Sir J. W. Swan, M.A., F.R.S.

Treasurer, John Sterry.

Ordinary members of the Council (erase not fewer than thirty-six names); *J. T. Ashby, *T. Thorne Baker, F.C.S., A. W. W. Bartlett, R. R. Beard, *H. W. Bennett, *C. P. Butler, A.R.C.Sc., Jas. Cadett, *C. Churchill, E. Leslie Clift, D. Cotes-Predy, M.A., W. E. Downey, Austin Edwards, Alfred Ellis, *P. H. Emerson B.A., *Douglas English, B.A., *T. E. Freshwater, F.R.M.S., *J. Fuerst, W. Gamble, *J. H. Gear, Dr. C. F. Grindrod, Captain H. C. Hall, Sir W. J. Herschel, *J. A. Hodges, E. T. Holding, F. Hollyer, *F. Ince, *Dr. G. Lindsay Johnson, M.A., M.D., *C. Barrow Keene, Rev. F. C. Lambert, M.A., *G. Lamley, *H. B. Lemere, Furley Lewis, *Ernest Marriage, W. Southcomb May, F. J. Mortimer, *J. C. S. Mummery, A. J. Newton, *C. H. Oakden, *J. Borthwick Panting, *J. I. Pigg, *Dr. T. C. Porter, *P. R. Salmon, Leslie Selby, *E. Sanger Shepherd, *C. W. Somerville, *John Spiller, F.I.C., F.C.S., John Sterry, Sir J. W. Swan, M.A., F.R.S., W. Thomas, *G. W. Tottem, T. C. Turner, *H. Snowden Ward, W. L. F. Wastell, Major-General Waterhouse, I.A., *B. Gay Wilkinson, J. W. Zaehnsdorf.

Judges—Technical and Scientific Section (erase not fewer than eighteen names): *T. Thorne Baker, F.C.S., T. Bolas, F.I.C., F.C.S., Geo. E. Brown, F.I.C., C. P. Butler, A.R.C.Sc., Jas. Cadett, *W. S. Colls, *Douglas English, B.A., *T. E. Freshwater, F.R.M.S., W. Gamble, *J. H. Gear, Dr. G. Lindsay Johnson, M.A., *Chapman Jones, F.I.C., F.C.S., Furley Lewis, F. J. Mortimer, A. J. Newton, *Wilson Noble, *E. Sanger Shepherd, *J. Spiller F.I.C., F.C.S., Dr. Spitta, A. H. Starnes, *Sir J. W. Swan, M.A., F.R.S., *E. J. Wall, H. Snowden Ward, *Major-General J. Waterhouse, I.A., *P. L. Waterlow.

The Selecting and Hanging Committee will consist solely of the seven judges elected by the members.

Fellows of the society are indicated by an asterisk. Balloting papers may be posted at any time, but only those will be counted which are received at No. 66, Russell Square, London, W.C., by 12 noon on Monday, February 13, 1905 (the day preceding the annual general meeting).

MR. FRED. W. EDWARDS, of Swadlincote, gave a lecture and demonstration before the Burton and Y.M.C.A. Photographic Society on Monday, the 6th inst. The lecturer, whose practical demonstrations are always popular with the members, chose as his subject "The Bichromate Salts in Negative Making," and the very able manner in which he manipulated the different experiments and processes proved that he was entirely master of his subject. In the course of his lecture he touched on the practical and theoretical aspect of negative making, and also described the chemistry of the chromium and bichromate salts, and the processes based on these salts. The judging of the prints entered for the competition, "Portraiture Without the Aid of a Studio," was then proceeded with. There was a good average entry, and some excellent work was shown. The silver medal was awarded to Mr. T. Grundy for a half-plate print on "Luna" paper, who also took second place. The next meeting will take place on Monday, February 20; subject, "Lecture by C. P. Goerz on Stereoscopic Photography."

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Feb.	Name of Society.	Subject.
10.....	Ulster Amateur Photo. Society	<i>Messrs. R. & J. Beck's, Ltd., Latest Novelties.</i> Mr. W. F. Slater, F.R.P.S.
10.....	Watford Camera Club	<i>Architecture Photographically, Technically, and Pictorially Considered.</i> Mr. H. W. Bennett, F.R.P.S.
10.....	Aberdeen Photographic Assn.	<i>Gay Pavee, Liéppé, &c.</i> Mr. A. Mackilloan.
13.....	South London Photo. Society	<i>Faking the Negative.</i> Mr. E. W. Taylor.
13.....	Optical Society	<i>Measurement of Absorption in Tinted Glasses.</i> Mr. L. W. Phillips.
13.....	Derby Photographic Society	<i>Demonstration by Mr. C. Barrow Keene, F.R.S.P.</i>
13.....	Southampton Camera Club	<i>Poona Prize Lectures.</i> Reader—The Hon. Secretary.
14.....	Royal Photographic Society	<i>Annual General Meeting.</i>
14.....	Sheffield Photo. Society	<i>Toning of Platinotype Paper.</i> Demonstrated. Dr. H. G. Paterson.

14.....	Glasgow Southern Photo. Assn.	<i>Annual Visit from the Photographic Section of the Paisley Philosophical Institution.</i>
14.....	Bristol Photographic Club	<i>Bromide Printing.</i> Mr. Fred Little.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held February 7. Mr. Leslie Clift in the chair.—In reply to a question by a member (arising out of the ballot paper for the election of council and other officers) it was stated by the chairman that the judges in the technical and scientific sections would act as the selecting and hanging committee in these sections only. In the pictorial section the selection and hanging will be done by a committee selected by the Council.

A demonstration lecture on the negative in architectural photography was given by Mr. H. W. Bennett, who very fully stated his own practice in this branch of work. He preferred to use a tripod with a large head rather than a turntable head on the camera. The legs of the tripod should be adjustable, and were best kept from slipping by a strut, which was greatly superior for this purpose to hooks or other accessories on the points of the tripod. The camera should possess a rise of front at least 3 in. in the whole-plate size, and should extend as far as 18 in. and as close as 6 in. A suitable battery of lenses for work in this size would be flat field anastigmats of 6 in., 8 in., and 11 in. focus, and Mr. Bennett said that the great majority of interior work would be done with the two lenses of shorter focus. In focussing, the largest aperture of the lens should be employed, and a point somewhat beyond the nearest object obtained in sharp focus. This point might usually be a distance beyond the nearest object equal to one-third the distance between camera and object. Exposure meters he found of very little use in ascertaining the time to expose the plate, owing to the variation in the depth of shadows with their distances from the camera. The most valuable hint in development that could be given was the use of a weak solution in cases of great contrasts. The normal solution might be diluted with eight times its bulk of water to the very great advantage of the negative in such subjects. The lecture concluded with a few very fine examples of architectural photography shown as lantern slides. These illustrated many of the points previously dwelt upon by the lecturer.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.
MEETING held February 2, at the White Swan, Tudor Street, E.C., Mr. T. E. Freshwater presiding. Mr. A. E. Smith gave a lecture on

"Photography with the Microscope." The lecture was illustrated by means of 12 by 10 prints from the original negatives, and by lantern slides reduced from the 12 by 10 negatives, and all were exhibited for the first time.

In enlarging with the microscope the procedure is in a general way much the same as in making a bromide enlargement, the microscopic objective taking the place of the usual negative, the sensitive plate being put up instead of the bromide paper. An easy method of finding the degree of amplification is to divide the focal length of lens by the length of camera extension. Thus using an objective of one-inch focus, with 50 inches camera extension, the magnification would be 50 times with a one-sixth inch objective, and 40 inches extension equals 240 times. It is always important to know the focus of an objective; those met with in commerce being generally marked too short, so that before any accurate calculation can be made the focus of objective should be carefully measured, the lecturer mentioning that an objective marked $1\frac{1}{2}$ was actually $1\frac{1}{8}$, a 2 inch was $1\frac{1}{2}$, a $\frac{1}{4}$ was $\frac{1}{8}$. When an eyepiece was used the magnifications are greater (with less camera extension), according to the power of the eyepiece, which gave usually 5, 7, 18, 27, etc., times more magnification; the lower the power used the better.

For small magnifications, up to about twenty times, a short-focus R.R. lens ($3\frac{1}{4}$ to $8\frac{1}{2}$ inches focus) will answer better than a microscopic objective. When using high power objectives, such as one-twelfth, a drop of oil is put between objective and object. This abolishes two refracting surfaces, but is messy. Achromatic objectives are corrected as regards the two chief colours, the apochromatic for the three. Mr. Smith did not use a projection eyepiece, as he found it too much trouble. A condenser he found useful, but not always necessary, the interposition of a sheet of ground glass giving the best results. Plates of 12 by 10 size were mostly used, the exposures varying from two seconds to two hours for transparent objects; from one to two hours for opaque subjects.

The light used was most important. Oil was too weak, but good and steady; incandescent gas was very good, but the mantle must be out of focus and secure from wobbling. Lime light was too hot and expensive. Arc light, from which great things are expected, proved disappointing, the arc being always in motion, and, except for short exposures, useless. The Nernst lamp is much better, but the light comparatively weak.

Then about one hundred slides were projected, the degree of amplification of each picture being given, covering a range from about 70 times to 90,000. All were of high technical excellence, as may be judged by the chairman remarking that he had never seen such a succession of splendid work, nor had enjoyed so pleasant and instructive evening. The 12 by 10 prints must have a highly educational value, and would enable the teacher to explain the special points required, in a manner quite impossible when the microscope itself was used.

Mr. Kinson was sorry that such work entailed the use of very expensive apparatus, but Mr. Smith and the Chairman were emphatic on the point that the extra expenditure, beyond a good stand, and one or two objectives, was quite unnecessary, and the hon. recorder promised to show on March 9 how a micro-enlargement could be made with simple arrangements.

Mr. W. Thomas was pleased to hear that Mr. Smith liked the Nernst lamp. Microscopic work was not his hobby, but he could speak with great pleasure as to the efficiency of the lamp for bromide enlarging.

On February 16, the London and Provincial will hold a smoking concert at the White Swan, Tudor Street, in place of the annual supper. The musical arrangements, it is satisfactory to note, are in the hands of Mr. T. K. Grant. Tickets for the concert cost one shilling each, and may be obtained from members or from the hon.

secretary, Mr. R. J. Kindon, Burnside, Church Road, Shortlands, Kent.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION—EDINBURGH BRANCH.

A MEETING of the Edinburgh branch of the P.P.A. was held at 38, Castle Street, on Friday, February 3, 1905. Present: Messrs. Crooke (chairman), Inglis, E. D. Young, D. Watson, Balmain, Heanen, Bibbs, Patrick, Banks, Russey, and Halkett.

The subject of assistants' certificates was taken up, when the chairman intimated that an almanac had been sent out by the P.P.A., embodying a scheme in regard thereto. Some of those present had not received it. A good discussion was carried on as to the examiners for the candidates, etc., the chairman remarking that a number of the subjects might be dealt with by correspondence. Mr. Heanen suggested that certificates might be granted both to male and female assistants, and also to receptionists. The abilities of the latter, however, as pointed out by Mr. Young, are greatly a matter of personality and would be difficult to deal with in connection with the more practical workers. The chairman strongly urged that as the chemical and optical department of the profession are of such importance, the candidates should give these subjects special study. In discussing the time of apprenticeship, it was thought by the meeting that three years was hardly long enough for their grade certificates, but during the currency of apprenticeship certificates should be granted in the various branches which would be so much (in hand) for the candidate. The meeting was quite unanimous in its approval of the scheme upon lines, however, which should be more fully discussed. It was also thought that the third and second grade (operators' and assistants') certificates might be combined.

"Cheap Portraits and the 'People's Friend.'" This subject brought forth a long discussion, several members being very desirous of knowing by whom they were produced. It was thought advisable that this matter should be dealt with by the P.P.A. by correspondence with the proprietors of the journal, pointing out to them the injurious effect such a system has on a great many photographers all over the country, as well as in their own town. The hon. sec. was therefore instructed to write the hon. sec. of the association to this effect, and with enclosure of circular. Mr. Balmain said it had come to his knowledge that the free portrait dodge had arrived in Edinburgh, particulars of which he would try to ascertain. A letter was read from Mr. Crawford as to conditions of fire insurance in connection with alterations, and classification of lenses, backgrounds, furnishings, etc.

ABERDEEN PHOTO ART CLUB.

UNDER the auspices of the Photo Art Club, a lecture was delivered last week by Mr. J. A. H. Hector, artist, in the School of Design, entitled "Picture Design." The lecturer, by rapidly-executed sketches on the blackboard, showed how from the simplest designs a great picture might be built up. By adding a light here and a shadow there, he demonstrated how a picture might be balanced, and how by certain lines the aim and motif of the artist might at one glance become apparent. The picture might be full of detail, but there should be one object which always brought the eye back to it. This object might be but a light in sky or landscape, a cloud or a group of trees; whatever it might be, one would find that the design of lines and balancing of parts led the eye naturally up to it. While insisting, however, on artistic design in picture making, he wished to make it thoroughly evident that such design should not obtrude itself on the eye—that "art should hide art" in such a way that the mind felt the beauty and purpose of the picture without knowing how such had been obtained. In portrait painting he showed that the same theory held good, that some design, pleasing yet unobtrusive, should run

through the picture. He said that sentiment and certain effects might be given to a picture, and by a few deft touches with the chalk produced a farm homestead, on a breezy upland, among sunlit sheaves, and explained the designing which had given the rising character to the landscape and the impression of sunshine and wind. Altogether Mr. Hector's lecture was a most instructive one, rendered all the more so that it was delivered purely from the point of view of an artist who claimed to know nothing of photographic methods. A cordial vote of thanks was accorded to the lecturer.

The lantern slides submitted in the competition, entitled "Play," were thrown on the screen by the lanternist, Mr. Stephen, while Mr. Duff read the criticisms by the adjudicators, Messrs. Findlay and David. The first place was given to Mr. Bow, the second to Mr. Stephen, and the third to Mr. Clerihew.

The Secretary received a letter from Mr. David, of Gray's School of Art, in which he suggested a slide competition of local architectural subjects, and the getting up of a set of such slides as would be useful in lecturing or teaching.

CROYDON CAMERA CLUB.

FEBRUARY 1, held at 128, George Street, a demonstration of real practical utility was given by Mr. H. P. C. Harpur, on the pictorial treatment of transparencies and lantern slides. The various methods of introducing clouds, shading down portions of the picture, double printing, and the like, were very clearly described by the lecturer. For general work of this description he used his enlarging lantern, and, in conjunction with this, a most ingenious easel of his own design was employed, adaptable to take from lantern size to 15 by 12 plates or paper, a notable point of this being that the carrier could be removed after focussing and replaced with certainty of correct register being maintained. Just behind the condenser of the lantern a sheet of finely ground glass was placed, to avoid any possibility of the image of the mantel recording itself; and reflection from the illuminated plate, or paper, to the highly-polished woodwork of the lantern and back again was obviated by covering the front of the lantern with velvet. This, Mr. Harpur said, was no needless precaution.

The most interesting point raised, however, consisted in Mr. Harpur's method of softening definition to any desired extent without the painful loss of structure, occasioned by placing the image decidedly out of focus. The method in question, consisted of placing, preferably close to the projection lens, and in front thereof, one or more thicknesses of French tulle. That sold at 6½d. a yard possessed the most suitable mesh, viz., 1-16 inch. It could be conveniently mounted on cardboard frames, and if more than one layer were employed, about 1-20 inch should separate each piece of fabric. When mounted, it should be steamed to remove the stiffening, which would also cause the material to tighten. One thickness did not perceptibly increase the exposure; two approximately increased it by one-half; three by three-quarters; and four doubled it. The soft effects produced in proportional varying degree, Mr. Harpur stated, were totally different to those obtained by bolting silk used close to the easel.

Irrespective of the softening of definition, a somewhat remarkable result also followed—namely, a considerable reduction of contrast in the enlargements. Whatever the reason of this may be, and it must be a purely optical one, the fact remains that Mr. Harpur convincingly demonstrated that negatives too harsh to be dealt with in the ordinary way, would be successfully enlarged by the method alluded to.

At the instance of the president, Mr. W. H. Smith, a most cordial vote of thanks was accorded the lecturer, and deservedly.

THE Photographic Exhibition at the Royal Albert Institute, Windsor, will be opened on Tuesday, February 14, by H.R.H. Princess Alexandra of Teck.

News and Notes.

A new photographic society is proposed for the Dennistoun district. The names of those favourable are being received by Mr. James Watson, 84, Bellgrove Street.

THE Secretary of the Northampton Exhibition writes that under an extension of time entries may be received up to the 14th inst. Pictures should be sent to the Town Hall by the 17th.

A LIST of stock-taking bargains is offered by the Tella Camera Company, of 110, Shaftesbury Avenue, London, W., who are clearing out hand and stand cameras, lenses, etc., at reduced prices.

WILLIAM HEATHCOTT BENTLEY, Ernest Bentley, and Charles Bentley, photographers, of Hanley, Staffordshire, and Nottingham, have changed their name to Humphriss.

MR. AND MRS. W. J. ANCKORN, of West Port, have just celebrated their silver wedding, which took place in 1880, that year also marking the foundation of their present successful photographic business.

PHOTOGRAPHING Royalty.—On the present occasion, as upon all previous visits to Ireland, his Royal Highness the Prince of Wales has honoured M. Lafayette with special sittings, thus bringing a most interesting series of portraits of his Royal Highness fully up to date.

RAILWAY Lantern Slides.—Lantern slides showing places of interest on the L. and N.W. line are available for the purpose of illustrating lectures, etc., and a list of slides and the terms on which they are loaned can be obtained on application to the Company's agents, or to Mr. R. Turnbull, Superintendent of the Line, Euston Station, N.W.

SLOUGH Photographic Society.—This newly-formed society, after successfully completing the programme for the first half of its winter session, has just re-started its meetings. The membership has increased, and an excellent record of attendance is maintained. Under the presidency of Mr. E. Oetzmann the society should have a very promising career before it.

At the Hull Photographic Society last week Mr. T. E. Kerridge read a paper on "Ischromatic Photography," in the course of which he recommended the home manufacture of screens, using Ilford black-tone lantern plates, fixed and washed, and soaked for three minutes in the solution of picric acid. For a twelve-times screen he used a saturated solution; for a six-times screen half strength; and so on.

THE Essex Field Club has inaugurated photographic and pictorial survey and record of Essex for the purpose of gathering together at the Essex Museum, Romford Road, West Ham, a permanent collection of photographs and pictures of objects of interest, with maps, plans, and other documents, so as to give a comprehensive survey and record of all that is valuable and representative of the county and of the neighbouring river and sea.

MR. T. WHITE, photographer, and Mayor of Lewisham, has recently had fame thrust upon him in his assumption of the rôle of stone-breaker. In order to test the genuineness of the complaints of unemployed who were put to stone-breaking by the Guardians, Mr. White and three other gentlemen became stone-breakers for part of a day, and though his professional duties did not qualify him for the task he did his turn in the yard without fatigue.

AN amusing and unrehearsed incident occurred at the first Drawing Room held by the Governor-General and Lady Grey in the Senate Chamber, Ottawa. An enterprising photographer, stationed in the Press Gallery, almost opposite the throne, ventured to take a flash-light photograph. The sudden blaze of light startled everybody, creating quite a sensation, and, according to one account, Lord Grey was so surprised that he nearly fell off the dais.—"Canadian Gazette." February 2, 1905.

IPSWICH Camera Club.—At the Museum last week, before a large attendance of members, presided over by Mr. G. H. Hewetson, a very interesting and instructive demonstration on the enlargement of photographs was given by Mr. A. W. Green, representing Messrs. J. J. Griffin and Co. Mr. Green also demonstrated the toning of bromide prints by the uranium and sulphide processes, and showed various apparatus connected with bromide printing. There were several ladies among the company, and all present manifested a close interest in the demonstration.

WE have received a comprehensive and well-printed catalogue and price list of enlarging and enlargements from the well-known trade enlarger S. H. Fry, of 12, South Villas, Camden Square, London, N.W. In its pages will be found details of the photographic work undertaken, all of which is executed under the personal supervision of Mr. Fry. The list includes quotations for enlarging and finishing in bromide, carbon, and platinotype, etc., and several special popular lines are also brought to the notice of the profession. Generous discounts are allowed to the trade, and the list will be forwarded post free to professional photographers.

At a meeting of the Thornton Heath Photographic Society, held at 86, High Street, Mr. H. P. C. Harpur gave a demonstration, before a large and appreciative audience, on "Portraiture by Window Light and Flash Light." For portraiture at home he recommended using a room into which the sun did not shine, or, failing that, only to work when the sun was obscured. When using flash light it was absolutely necessary that the light should be diffused, and the full aperture of the lens should be used to secure softness. If magnesium ribbon be used for the illuminant, it should be kept in motion during the exposure, even when diffused through a screen, otherwise uneven lighting would result.

THE London County Council's improvements in London having swept away many historic buildings, it was to be expected that the Council would not overlook the making of a photographic record. Inquiry, however, on the part of Mr. Hector Maclean, as reported in the "Morning Post," discloses the fact that such photographs as the Council possessed are scattered about various departments. No permanent photographic specialist has been appointed, and it is understood that the records are printed in silver. It should not be necessary to inform even local government authorities that silver prints are unsuitable for this purpose, platinotype or carbon being the printing processes universally recommended.

At Bromley, Kent, one day last week, the magistrates investigated some extensive thefts of photographic apparatus. The stolen property was of the total value of nearly £30. The accused, against whom there were four separate charges, was Walter Ware, residing at Broom Hill, Orpington. He had not been regularly employed for some time past, and Mr. Richard Cartright Davenport, the prosecutor, a tradesman of London Road, Bromley, had found him occasional employment. The prisoner took advantage of his visits to prosecutor's premises to rob him of goods in a wholesale manner, and then pledge them. The prisoner pleaded guilty, and was sentenced to six months' hard labour.

THERE was an influential gathering of City men at Anderton's Hotel on Friday last, when Sir William Treloar, on behalf of a large number of friends presented Mr. W. G. Thame, the late advertisement manager of the "Standard," with a handsome testimonial as a mark of their esteem. The presentation took the form of a valuable gold hunter and chain, and an illuminated address, while a diamond bracelet was subscribed for to be handed to Mrs. Thame. Sir William Treloar, in offering the tokens to Mr. Thame, whose birthday it was, mentioned that he had known the recipient of their good wishes for very many years. That gentleman used to induce him to spend a good deal of money in advertising, and he felt it difficult to dissociate him from the occupation their guest had so ably followed.

He (Sir William) had been looking up some old newspapers, and found that forty-one years ago his father had a shop on Ludgate Hill which the Chatham Railway Company acquired when they put a bridge across that thoroughfare. His father brought an action for compensation, and in his evidence he said a good many things about advertising which were interesting. He gave it as his opinion that advertising in a certain number of years repaid to the extent of 10 or 15 per cent. Advertising was a science which it was necessary to study, and although it would not return profits for some time, it soon did so. His father also told the judge that he had had a gentleman in his shop who carried a newspaper seven years old, and pointed out that a considerable purchase resulted from the perusal of an advertisement published seven years before it reached the eye of his customer. Some years back Sir William Treloar said his income-tax assessment was doubled. He appealed, and found the commissioners not very wide awake. It was not so now—he spoke as an income-tax commissioner. (Laughter.) Asked why they overcharged him, one of the commissioners produced three copies of a paper in which he had whole-page advertisements, and said: "It is impossible to spend a lot of money like that unless you have a large income." He laughingly replied, "It shows you know nothing about it. These advertisements are flags of distress which I show when I want business." Sir William concluded his speech by expressing the delight he felt at being able to make the presentation to their esteemed friend, whom they were delighted to see in good health. Mr. Thame, in returning thanks for the gift, expressed pleasure at being honoured by so many of his old friends and colleagues.

Commercial & Legal Intelligence

TORQUAY Photographer's Failure.—The first meeting of creditors and public examination in bankruptcy of Samuel James Porter, photographer, 4A, Strand, Torquay, were held at Exeter recently. The gross liabilities were stated to be £2,476, expected to rank for dividend £622, assets £235, deficiency £386. The causes of failure alleged by debtor were: "Depreciation of property, and being obliged to move my Torquay business; heavy rental of Torquay business premises." The official receiver, in his printed observations, stated:—"The debtor states that he commenced business at Ventnor, Isle of Wight, in 1890, with a capital of about £190. About seven years ago he opened a branch at Torquay, five years ago another at Paignton, and three years since one at Exeter. He sold the Ventnor business about two years ago, the Paignton business in September last, and the Exeter business in November, 1903, the Torquay business being the only one now carried on by him. He says he has not balanced his affairs at any time, and there is no account showing the profits from his trading; that he did not become aware of his insolvency until a fortnight ago, when he found that he could not sell his Ventnor property except at a loss, and that he should be liable for the balance due to the mortgagee. The fully-secured creditors include the bankers for £134 7s. 8d., who hold a guarantee, and the guarantor holds as security for that and his own debt of £54 6s. 9d., two bills for £135 given by the purchaser of the Exeter business, and six bills for £10 each given by the purchaser of the Paignton business. The last of these bills falls due in July, 1906. There are two fully-secured creditors for £900, holding first and second charges on a freehold house at Paignton. The partly-secured creditor for £710 holds a mortgage on a long leasehold house at Ventnor, of the estimated value of £550. The landlord of the Torquay premises is a creditor for £180 balance of rent to Christmas last, of which he claims in full six months' rent. £112 10s., and as security for the remaining rent he holds a life policy worth about £15, and three bills amounting to £100, part of the purchase-money of the Paignton business. The unsecured creditors for sums over £10 each include three for £194 for money lent, one for £15 for furniture, and the remaining creditors are all for goods supplied."

THE R.P.S. AND REFORM.

To the Editors.

Gentlemen,—There is a very impressive sound in the expression "Reform Committee." One instinctively assumes it to consist of a small body of individuals chosen for their abilities and general worthiness to represent a community at a period when misgovernment has reached a stage beyond endurance, with a view to the establishment of an improved system which shall avoid the errors of the past and result in enhanced prosperity to all concerned. That is what a Reform Committee should be to justify its name, and, in order that it may perform its function truly, it must be composed of men of wisdom, experience, and, beyond all, of probity. A body so composed would certainly not undertake to upset existing conditions without a clear aim, a definite policy, and a fulness of assurance of being able, not only to make a change and create a new system, but to make a change that shall be beneficial, and to create a new system which shall be an improvement on the old one. The border-line between reform and meddling interference is very lightly drawn; sometimes at first it is imperceptible, but after a time, in the broad light of day, it "prints out," and does not require any toning or fixing. Thus it is only by waiting for the result that it is possible for the uninitiated onlooker to form an opinion whether a movement, represented to be a reforming one, is genuinely of that nature, or whether it is merely a revolutionary movement of the character which South American Republics have taught us can easily be brought about by aspiring politicians in their own interests; and, now that sufficient time has elapsed to be able to judge by results, in the interests of everyone concerned in the prosperity of the Royal Photographic Society, and in ordinary fairness to those gentlemen whose voices were so loudly heard in 1892 in protest against a state of things which, in their wisdom, experience, and probity, they thought or said they were capable of improving, it is fitting that their claims should be considered, either to be looked upon as men of wisdom, experience, and probity whose names deserve to be recorded in history, or—well, merely as interfering meddlers.

It was rather more than three years ago that the then president of the R.P.S., in a manner which the Council contended was unconstitutional, proposed certain alterations in the constitution of the society, which the Council almost to a man opposed as being more likely to do harm than good. A "Reform Committee" sprang into existence, declared battle against the Council, and in the end ejected them bodily and filled their places with its own nominees. If this was "reform," the results of the last three years ought to show that the Reform Council has done better service than its predecessors, that it has raised the society both in status and material prosperity, that it has become more useful to its members, and that it more completely fulfils its mission—the advancement of photography.

A comparison of the work of the last three years with a corresponding period before the "reform" will tell its own tale.

In 1898 the Council organised an exhibition at the Crystal Palace on a scale that had never been attempted before in connection with photography. That it was a brilliant success was undoubted, and that all concerned were entitled to the highest praise has been everywhere enthusiastically acknowledged.

In 1899 the Council, in view of the fact that the growing importance of the society demanded better house accommodation, entered into the tenancy of 66, Russell Square. The cost of furnishing and

equipment was provided by an appeal to the members, which was so abundantly responded to that it was only found necessary to call up one-third of the amount promised. This, at any rate, showed that the Council possessed the confidence of the members generally and their approval of the undertaking.

In 1900 the Council, after strenuous efforts for years to find better accommodation for the exhibition than at Pall Mall, transferred it to the New Gallery, Regent Street, as epoch-making an event in the history of the exhibition as that just referred to was in the annals of the ordinary work of the society.

In 1901, in spite of the interruption of the work of the winter session caused by the proceedings of the president and the Reform Committee, at the time of their forcible exit in February, 1902, the Council had arranged and ear-marked the funds for:—

The provision of enlarging apparatus; the arrangements were partly made.

The publication of a catalogue of the library; this, again, was in hand.

The arrangements for proper display of the Museum and the permanent collection of pictures.

The arrangements for a series of lectures of an elementary or demonstrational character for the benefit of the less advanced members was discussed, but postponed for a reason of a transitory nature.

Exigencies of space have restricted this list to practically one item of each year's work, but it does not require much discrimination to recognise that the important changes indicated and the corresponding expansion of the society must have entailed an enormous amount of actual work and a not inconsiderable display of administrative ability. Against this unduly epitomised record of the old Council's achievements let the achievements of the Reform Council be set out. There is no need to epitomise. They can be set out in full.

The Reform Council has completed the arrangements of the enlarging room.

It has carried out successfully the arrangements of the museum and library.

It has almost completed the library catalogue.

It has instituted the series of practical demonstrations.

These, its successful efforts, were the legacy of its predecessors, and it must be said they have been well done.

It instituted the custom of publishing a brief report of the proceedings of the Council, a valuable innovation, but discontinued for some reason more or less obvious.

It attempted to institute an Annual Dinner, and failed.

It has attempted to raise funds for a research laboratory, with little prospect of success.

The celebration of the society's jubilee in 1903, an unprecedented opportunity for a demonstration of the most brilliant description, was utterly wasted. A dinner, sparsely attended; a Conference in the society's rooms, at which a few ordinary papers were read to an assemblage of a couple of dozen or so; an exhibition of historic apparatus, consisting of a few cases containing a few dozen articles—the whole proceedings, conducted in an atmosphere of funereal gloom, constituted the jubilee celebration.

Possibly some unimportant item may have been omitted, but on the whole this is a fair record of the Council's activity during three years. For the consequences to the society, please refer to the report and balance-sheet just issued. To men whose coming was heralded by the Reform Committee with such flourish of trumpets this must be a most humiliating document. A confession of failure in every direction. Stagnation in the work, falling receipts, enhanced expenses, the unprecedented number of resignations of membership, fifty-seven in the year, a balance on the wrong side, and dry rot everywhere.

It is on this record that a Reform Committee, engineered mainly

by the same individuals who, in 1902, beguiled the members into entrusting the society's management to their care, dares to appeal for support for themselves and their nominees.

The entire facts have never been disclosed with regard to the revolution of 1902. At the time it was represented that the opposition of the Council to the president's wholesome proposals was entirely fractious. Let us review the results of carrying out these proposals. The battle raged round two points in particular—the abolition of the office of honorary secretary (the original scheme provided that the secretary must be a paid officer; the permissive wording of the rule was introduced later: if the rule had been presented at first as afterwards modified there would have been no necessity to oppose it), and the publication of the nominators of candidates for the Council. With regard to the first, in the time of the old Council the secretarial and clerical work of the society was performed, and performed efficiently, even during the great changes which have been recorded, and which necessarily involved a considerable addition to the ordinary amount of clerical work at an expense of about £150 or £160 per annum on the average. A speaker on the reform side, whose testimony is unimpeachable, stated publicly that the hon. secretary was a hindrance rather than an assistance to the assistant secretary, so it may be assumed that, at any rate, the new conditions involved no necessity for greater expense. No question of cost was raised, however; the point of the contention of the Council was that the work could be *less efficiently* done with an officer not directly responsible to anyone. Well, the alteration in the status of secretarial department had for its first effect an increase in the cost of the department to £250, and according to the last balance-sheet the cost has now reached £312 for the year.

The point remaining is the publication of the nominators' names. It is only necessary to turn to the lists of Council for the past three years to discover the erratic way the members exercise their privilege of voting. A man does something to bring his name into temporary notoriety. In February he is popped on the Council. The next year he is popped off. His capabilities as an administrator no one knew, knows, or probably ever will know. A chandler's-shop keeper will not engage an errand boy without a reference to someone who knows something of him. The members of the R.P.S. are expected to choose their representatives from a list of names whose owners mostly would seem only to have the recommendation that they aspire to govern. The old system was not perfect; it was capable of abuse, but at the worst it never could lead to the chaotic confusion of the present method. For results, vide the report and balance-sheet.

The present Reform Committee is a very human institution after all. A number of gentlemen, estimable enough in their way, who have never done anything to induce anyone to imagine they possess more than ordinary capacity—some on the Council, and fearful of losing their seats; others, not on the Council, but aspiring—meet to consider the best way they can advertise themselves for their mutual benefit. "The Manifesto of The R.P.S. Reform Committee" is the result. There is the matter in a nutshell.—I am, etc.,
RESPECT FINEM.

WHAT TO DO WITH OUR GIRLS.

To the Editors.

Gentlemen,—A few weeks ago there was a letter published in your journal from a father who was anxious to start two of his daughters with a photographic studio.

My sister and I are carrying on a successful business of our own, and if I can be of any assistance to others wishing to do the same I should be glad to do so.

Enclosed is name and address if you care to forward.—Yours truly,
February 7, 1905.
SCRIBBLER.

THE FOCAL-PLANE SHUTTER.

To the Editors.

Gentlemen, -I should like to express my appreciation of the technical and scientific turn the BRITISH JOURNAL has taken lately. I read with great interest the articles on the focal-plane shutter; but although the first notice was very good, I must say the method of treating the subject seems to have led to much obscurity in the second article appearing in the current number. I should like to ask the author how the third row of figures in the table the "illuminations," are arrived at. It is true he states, that "no exact mathematical treatment of the problem can be given," but why not, may I ask? The statement is made that if the width of the slit equals half the diameter of the diaphragm ($s = \frac{1}{2}b$), then the illuminations are the same at double and normal focus. This is quite true, if by "illumination" is meant the duration of exposure multiplied by the efficiency of the shutter; but just previous to this statement an example is given where the width of slit is 1 c.m., and the surface illuminated at double focus 4 c.m. Now obviously under these conditions s does $\neq \frac{1}{2}b$, and yet the author deduces $\frac{1}{2}$ as the value of the illumination. Now it must be borne in mind that a back extension would very probably be used in conjunction with the back half of a symmetrical combination, and then although the illumination would be the same, regarding illumination as a shutter factor, yet, on account of the altered value

of the diaphragm, twice the exposure must be given. One might naturally think the exposures would be proportional to the illuminations, therefore I think this term somewhat unsatisfactory. But if we understand what is meant, it matters little, and, as I will show, the "illuminations" are practically the same whatever the position of the blind shutter in the camera. And this is where I seriously differ from your table.

The simplest way of dealing with the question of "efficiency" and "illumination" is to consider the light-action at a point instead of at a surface of considerable area; then there will be no "crossing rays" to muddle one's mind. Imagine that a star were being photographed, and in accordance with the rules of geometric optics, which are all-sufficient for this little problem, make a sketch of the parallel beam of light converged to a point on the sensitive plate. Let the image of the star be in the middle of the plate, and also, so that conic sections and their areas shall not obtrude in any way, imagine we are using a square diaphragm. Now the efficiency of a roller blind shutter is the number of times the width of the pencil or beam of light where the shutter cuts it, is contained in the width of the slit divided by this number plus 1. Thus, if the shutter slit is the same width as the pencil the efficiency is $\frac{1}{1+1} = 50$ per cent.

Now, in the figure let a = aperture, and w the width of slit. Let

the blind cut the pencil LPL' in any plane between a and P. Supposing the plane of the shutter $1/n$ th. the focus of the lens from the plate, and taking the speed of the shutter at the focal plane as unity, the speed at the plane ss' , $1/n$ the focus from the plate, will be

$$\text{duration} = \frac{w + \frac{a}{n}}{w}$$

But the efficiency in the same plane is $\frac{w}{w + \frac{a}{n}}$; the width of the

slit divided by the width of the slit plus the width of the light-pencil.

Hence the illumination equals

$$\text{duration} \times \text{efficiency} = \frac{w + \frac{a}{n}}{w} \times \frac{w}{w + \frac{a}{n}} = 1.$$

Hence my disagreement with the third row of figures, the illuminations, in your table.

It will be seen that if we substitute $\frac{1}{n}$ for $\frac{1}{n}$, the duration

$\frac{w + \frac{a}{n}}{w}$ becomes $\frac{w + \frac{a}{2}}{w}$, which gives the values in your table of the relative speeds, with which I am in perfect agreement.

My conclusion is, therefore, that although the speed varies considerably with the position of the blind in the camera, the effective exposure does not vary. Further, if a back extension is used to adapt the camera to the varying foci of a convertible lens, the exposure will vary in accordance with the altered value of the diaphragm.—Yours truly,

C. J. STOKES.

29, The Green, Richmond, S.W., January 31.

HONORARY PHOTOGRAPHERS.

To the Editors.

Gentlemen,—I beg to enclose a copy of my reply to the letter by the editor of "Woman's Life," which appears in your last issue. Why will not these editors stick to their lasts and let photographers alone?—I am, dear sir, yours very truly,

A. J. LANGTON.

The Langton Portrait Studios, 35, Buckingham Palace Road, Belgravia, London, S.W.

To the Editor "Woman's Life," Southampton Street, Strand.

Dear Sir,—Replying to yours of even date re free photograph scheme. I wonder if you would do what you calmly ask me and other photographers to do? It is a faulty rule that will not work both ways, so what do you say to this "scheme"? I propose to give a coupon with each photograph I supply to the public. Three of such coupons when presented to the Editor of "Woman's Life" will entitle the presenter to at least one shillingsworth (my photograph would cost me about 2s.) of the publications of George Newnes, Limited. "You will, of course, readily perceive that this introduction by us paves the way for further remunerative business on your part."

Candidly, if you do accept my proposal, I should think you as big a fool as I should know myself to be did I accept your exactly similar scheme.—I am, dear sir, yours truly,

A. J. LANGTON.

WEEK-END Holidays from London.—A handy pocket guide is in course of preparation entitled "Week-end Holidays from London." It will contain exactly the information which the week-end traveller needs, namely, brief particulars of a large number of the most popular South and East Coast resorts, together with the fares and train services, as officially supplied by the railway companies, and the week-end charges made at hotels, hydros, and other establishments. Two editions of the book are to be issued yearly—the first at the beginning of May and the second in October.

Answers to Correspondents.

- * *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.*
- * *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- * *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.*
- * *For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

PHOTOGRAPHS REGISTERED:—

- J. Haywood, Kingswood, Wooton-under-Edge, Glos. *Photograph of Loom and Maker together with Designs of Ribbons made in the Model Loom, together with Description, all forming One Picture.*
- R. Leak, 60, South Parade, Bradford, Yorkshire. *Photograph of Group in the Comic Opera, "The Mandarin."*
- M. D. Morley, 94, Belgrave Road, Leicester. *Two Photographs of General Buller Unveiling Monument at Nuanetsi.*
- S. J. Jones, 9, St. James' Street, Newport, Isle-of-Wight. *Photograph of a Soldier Holding a Wild Ass called Kyang, Captured at Lhasa in Tibet.*
- W. H. Dee, 810, King's Road, Reading. *Photograph of the Reading Football Club.*
- H. Gascoe, Ltd., 48, Queen Street, Wolverhampton. *Three Photographs of Mr. Henry Norman, M.P.*
- F. W. Hardie, 416, Union Street, Aberdeen, N.B. *Photograph of the late Mr. E. Brough, A.R.S.A.*
- C. Johnson, High Street, Gillingham, Dorset. *Photograph of A. W. Wills, Esq., M.P., North Dorset, and Party in Motor Cars.*
- H. P. ROBBIE.—We do not know the address. Better write to the Y.M.C.A. Camera Club, Alexandra Hall, Cambridge.
- H. H.—We cannot be the medium of communication of the kind you send. We have destroyed your letter.
- L. S. LANGFIER.—The Westinghouse Company, Westinghouse House, Norfolk Street, Strand, London, W.C.
- J. W. STAREY.—We should advise you to obtain provisional protection, which you can do for a sovereign; then apply to such houses as Fallowfield, Hurman, Houghtons, etc.
- A. QUERIST who asks for the wages of a lantern slide colourist is informed that such work is generally paid for by the dozen, and the price paid by some firms is about 3s. or 4s. a dozen.
- C. J. D.—We do not undertake commissions of the kind you name in your letter, but if you will turn to the "Miscellaneous" advertisements in the JOURNAL, you will see offer of service such as you require.
- A. F.—The postcard is a rather bad colotype. You can obtain cards in colotype from a number of firms. It is not usually so cheap as half-tone. You will see prices for both processes in our advertisement pages.
- AGRI.—There is not the slightest advantage in using a dilute developer. Use one of the normal strength and without bromide. You would get much better results if you used the special X-ray plates made by the same firm as those you are now using.
- PHOTOGRAPHIC ENAMELS.—Can you inform me where I can obtain particulars of a process for transferring a photograph on to enamel or porcelain which will stand burning?—G. A.
"Photo Ceramics." By W. Ethelbert Henry and H. Snowden Ward. Published by Messrs. Dawbarn and Ward, 6, Faringdon Avenue, London, E.C. Price 1s.
- RUDOL.—Will you kindly inform me where I can obtain some of the new developer, Rudol, mentioned in this week's Journal?—WM. H. COX.
The name of the maker is Dr. C. L. Marquart, Beuel-on-Rhein. We shall be glad to see the prints, and will then deal with them.

ANON.—The seaside season begins in May and June, as a rule, and there is not much to choose between places as to date of commencement. As a rule you will see plenty of advertisements in the "Situations Vacant" column for the seaside season, and we should advise advertising about the middle of April.

ARCHITECTURAL POSTCARDS.—Could you oblige me with the address or addresses of firms publishing architectural views of London or other cities in England on postal cards?—A. LEVY.

Application might be made to the Photochrom Co., Cheap-side, E.C.; Valentine and Co., 154, Perth Road, Dundee; Hood and Co., St. Bride Works, Middlesbrough.

CLAIM OF SALARY.—Will you kindly inform me if I can claim a week's salary, in lieu of notice, in the following case?—I was engaged by letter, at a weekly salary, as retoucher and spotter, no mention of going on trial in it. It was at a very busy, cheap photographer's, and at end of week, finding the place much too hard, I gave a week's notice, and was immediately told that I need not come on the following Monday as I did not suit. I may add that I was told there were three retouchers kept, but found when I got here I was the only one, and was expected to get through about fifty negatives a day, and last three days of week had 600 to 700 prints a day to spot.—Y. Z.

As you were engaged at a weekly wage, although there may not have been any definite statement as to notice, there is an implied contract which would enable you to claim.

RETOUCHING.—Kindly examine enclosed prints and give me your opinion of retouching on same; also state the quality of the lens the photographs have been taken with.

(1) Prints sent for criticism of retouching should comprise a double set, the first showing the unretouched state, and the second set displaying the effect of the retoucher's efforts; otherwise, it is impossible for us to form an idea of how you have treated the likeness and general character. Your retouching is decidedly very weak, but shows promise of better things in certain respects. You are too undecided and flabby in your technique, but a few first-class lessons from an expert teacher should soon put you on the right road to success. (2) It is impossible to say much as to the lens because no details are given of the aperture used, but there is not, so far as we can see, much fault to find with it.

COLLOTYPE.—Wishing to gain some information respecting the "Colotype Process for Postcards," which is described in the BRITISH JOURNAL PHOTOGRAPHIC ALMANAC, 1905, p. 915, I should feel much obliged if you would be so kind as to send me formula for colotype ink and colotype varnish? Then I have tried ordinary writing ink and copying ink, but I cannot get any copy.—VILHELM WARDINGHAUSEN.

We recommend you not to attempt to make the ink or varnish in the small quantities you probably require. Your wisest course is to procure from the dealers in process supplies, such as Klimsch and Co., Frankfort-on-Maine, Germany, Penrose and Co., London, or through your local stationer. You may purchase lithographic ink and varnish with less difficulty, and these will answer your purpose almost as well. Writing and copying ink are quite useless; why not get a book on the colotype process.

INSERTING PORTRAIT IN GROUP.—A customer has a family group, he is coming to sit himself, and then he wants me to take one figure out of the group and put him in instead. How should I set about this? I intend taking him the correct size for photo of group; but then I do not know if it would be best to make a print of him, cut it out round the figure, paste it on the group over the other figure, and then copy the whole, or whether I should cut figure out of film, and, after removing the film of

figure that is to come out of group, stick the fresh piece of film in its place in group negative. The former seems the easiest, but there may be other ways.—GLAUCUS.

The former is the better plan. The print of the figure should be taken on the thinnest albumen paper and, after cutting out, the edges should be rubbed down with fine sandpaper. The junction of print and figure will then scarcely be visible, and if you copy the composite print with the light falling flat on it, the join will not show in the negative.

PROJECTION.—At a distance of 10.5 mètres I want to get a picture of 3.5 mètres, the transparency being 7 cm. in diameter. Is it possible, or, rather I should say, practicable, to do so, that is, with sufficient brilliancy and sharpness and not excessive distortion? It is evident that a small diaphragm would increase the amperage and consequent heat and cost of light beyond feasibility. I have an old portrait C.D.V. lens that does it, but sharpness insufficient. What is the easiest way to find the back focus of this portrait lens?—PHOTOPHIL.

This is a matter of calculation; thus $10.5 \times .07 = 3.5 \div 21$ centimètres, which is the focus of the lens required to give the above-named disc, the rule being multiply the distance between lens and screen by the diameter of the transparency and divide by the diameter of disc. We do not quite understand what is meant by the small diaphragm increasing the amperage. If the C.D.V. lens does not give sufficient marginal sharpness, the back combination should be unscrewed and the lenses separated a little more, and, by trial and error, using rings of cardboard, the best separation can easily be found. To find the back focus, focus the sun or clouds as sharply as possible, and then measure the distance between the focussing screen, or even a white card may be used without a camera, and the back glass of the lens.

TINTYPE.—I shall be glad if you would give me some information as to the following:—I have been out of work now for over a year, and, being unable to obtain any, I want to try and do tints at the seaside during the summer. The information I want is the probable cost of a complete outfit, and where they can be obtained, and if you would give a little information as to the working I should be grateful. I have been a practical photographer over thirty years, and for nearly twenty-seven with one of the leading West-End firms, but the process I am asking about is to me a novelty. Some seaside places are, of course, better than others. If you can give me a hint I shall be glad.—SHADOW CATCHER.

The ordinary tintype or ferrotype process could be adopted, but this entails learning the wet collodion process, if our correspondent does not already know it, and also the purchase of a portable dark room. If, on the other hand, the dry ferrotype process were adopted, all that would be required would be the special camera and plates, and Jonathan Fallowfield, of 146, Charing Cross Road, London, W.C., is the agent for these, and full description and prices could be obtained on application. With regard to the best pitch, we are afraid we cannot give any assistance.

COPYRIGHT.—Could you kindly inform me the method of getting a copyright for a Christmas card that I have designed? The points I should like to know are (1) the cost; (2) where I should have to send; (3) whether it is necessary to do another card, which I want to avoid if possible, as it entails a large amount of time and work.—XMAS.

It is impossible to answer satisfactorily, because we are in doubt what is actually meant by "design"; as this might entail protection as a design, when it would have to be registered in the Trade Marks and Designs section of the Patent Office, Southampton Buildings, Chancery Lane, W.C. On the other

hand, it might be classed as a work of art, and would then fall under the ordinary Copyright Act. In any case, we should advise the sending of a stamped, addressed envelope, and a penny stamp, to the Registrar, Stationers' Hall, London, E.C., for a "memorandum for registration under Copyright (Works of Art) Act." This form must be filled up and sent with a postal order for one shilling to the above, when doubtless it could not be copyrighted the Registrar would inform you, if you send a stamped, addressed envelope. It is not absolutely essential to send a print or anything else that is to be copyrighted, but it is, we think, preferable in the case of a photograph, and possibly a photograph of the "design" might be appended in this case.

MISTAKEN RIGHTS.—I took the enclosed photograph of the matron and nurses at our local hospital to their order—viz., eight dozen p.c.'s, which I said I would do at 3s. 6d. per dozen. I first submitted $\frac{1}{2}$ -plate proof, which I enclose. They liked same, and told me to go on with the p.c.'s. I first made one as enclosed and submitted, and they ordered from same eight dozen. When finished I sent in my account, and 5s. for going out and first proof, saying the p.c.'s were ready. At this they were highly offended. First, because I did not send work before payment. (This is one of our terms, and shown in large type in all our premises.) Second, because I charged 5s. for taking same. Thirdly, they affirmed the p.c.'s were not purely photographic ones, and they could get exactly similar in Liverpool for 25 a 1s. At this I refused to supply them with the p.c.'s. I then put them on sale and sold them well, up to date about twenty dozen, from just before Christmas. Now, can they stop me selling same and exhibiting for sale? If so, my directors say they must pay us 10s. 6d. for going up to take photo and the proof. Can I legally claim same? I have proof that they sent many people to buy the p.c.'s for them. Kindly inform me what is my right course.—CLIFTON JOINT.

It seems to us that you are wrong from beginning to end. You contracted to supply a certain number of the cards at a stated price, therefore you were not entitled to charge anything for the $\frac{1}{2}$ -plate picture, which was not ordered. You should have delivered the cards as ordered, and then if not paid for you could have sued those who ordered them for the money in the County Court. Instead of this you refused to supply them at all. You have also done wrong in selling the pictures. The copyright in them is vested in the customer who ordered the picture to be taken, and whom you could have sued for the money. You had no right to use the customer's pictures for your own purpose, and they can stop the sale of them. You cannot, of course, claim the sum suggested by your directors.

NOTICE.

Several replies are held over for insertion next week.

EX CATHEDRA.

Another Art Find. More than once we have alluded to the probability that there may be large numbers of valuable pictures in existence, by painters of renown, the owners of which do not prize them, as they have no idea of their value. We read that one was recently bought in the neighbourhood of Swindon for a mere trifle, which proved to be a picture by the celebrated artist, Paul de la Roche. It bears the inscription, which was almost illegible when purchased, "Duchesse d'Orleans—Paul de la Roche." It is said that the picture has been purchased by the Duke of Orleans, and that it is without doubt a family portrait. There is little question that there are scores of pictures by renowned artists in different parts of the country that are treated by their owners more as lumber than anything else, and who would willingly exchange them for a brightly-coloured modern "chromo," which would be more in accord with their ideas of a picture.

* * *

The Rapid Copying of Plans. Lecturing to the students at the Bolt Court School of Photo-Engraving last week on his Indian experiences in reproduction work, Major-General Waterhouse mentioned that when in America recently he had noticed the use which was made of gaslight paper for the copying of large plans and drawings. A negative was first made by contact with the original exposure of a few seconds to arc-light was sufficient for this purpose, and the negative thus obtained was immediately printed on to a second piece of gas-light paper. Apparently this was done with the back of the negative in contact with the face of the sensitive paper,

both being wetted, and apparently also the negative was not fixed. The whole process, General Waterhouse stated, was complete in a minute or two. The cost of gas-light paper seriously interferes with its use on a large scale for such purposes as this, and we are not at all sure that in continuous printing the process would prove economical of time. But in "rushed" work it may probably be of service, and it is, therefore, well to note that gas-light papers by their harder contrasts are more suitable for the reproduction of line-drawings than are those carrying the usual bromide emulsions.

Foreign Picture Postcards.

Some time ago, since the picture postcard has become such an institution in this country, our postal authorities allowed a portion of the address side of the card to be utilised for correspondence. The cards now bear an intimation that this applies to inland postage only. Now, we learn that Germany has followed the example set by this country in the matter of picture postcards, and, from the beginning of this month, the address side of the card may be utilised for correspondence, provided the space be marked by a clear, perpendicular line, and that not more than half the card be so used. This concession by the English and German authorities is in one way a great advantage, as it permits the whole of one side of the card being filled by the picture. Whether the recent concession by the German postal authorities applies to picture postcards, written on the address side, and sent from this country, seems somewhat open to doubt; or whether a German one sent here would be delivered without a surcharge is, at present, not quite clear.

* * *

Postcard Piracies.

There is one aspect of this concession of the German Post Office which has escaped the notice of the lay Press, but which is of considerable importance to photographers. It concerns the use of copyright photographs on postcards. Under the German copyright law licence is granted to copy and reproduce any photograph "for use in a work of industry, handicraft, or manufacture." And it has been held that a postcard is such a work of manufacture, and the publisher thereof is empowered to lay hands on the work of any photographer and use it for the decoration of his goods. That such a practice should be countenanced is the more unfair when it is remembered that a considerable proportion of the total vast issue of pictorial cards does not go through the post at all. The cards are bought and preserved for their pictorial qualities, not utilised for their legitimate purpose. And, again, the picture postcard as usually produced, allows very little space for a written message; so little, indeed, that the reproduction of a copyright photograph under these conditions has been contested in the

high German Courts, but unsuccessfully. Now that the message can be written on the address side of the card such action becomes more hopeless still, since the back can be filled with the picture to the edges without the "post-card" character disappearing. In the eyes of the German Government a picture postcard is an article manufactured for the transmission of written messages, and the piracy by the publishers of photographers' copyrighted work is more firmly established than ever by the recent concession of the Post Office.

Using Negatives Without Permission.

It seems that the law in France is pretty much the same as it is here with regard to the right of a photographer to make use of customers' negatives, for his own purpose, without their consent. A judgment was given one day last week in the Paris Law Courts in the action brought, a little time back, by Dr. Doyen, a well-known surgeon, against some manufacturers of cinematograph films. It seems that the doctor, for scientific purposes, had certain operations, performed by himself, cinematographed. Some time afterwards he found that the films were being sold for public exhibitions, and he at once instituted legal proceedings. In the result the Court decided that Dr. Doyen in the sole proprietor of the films, and that he can restrain them from being exhibited against his wish. The Court also decided that he had suffered moral detriment by their being exhibited at non-scientific assemblies, and the defendants were ordered to pay substantial damages. Two of them have to pay the doctor 8,000 fr., another 500 fr., and a fourth 200 fr. These are very substantial damages, but none too much, one would think, under the circumstances. In the English and Scottish Courts it has been held that photographers have no right to exhibit, or sell, copies of portraits of customers, or to make use of them for any purpose of his own, against their wish, and injunctions have been granted restraining their doing so. No damages in these cases were given, as none were sued for, so far as we are aware, but when an injunction, with costs, is granted in the Court of Chancery, the latter is a matter that the defendant is not likely to forget, as they always amount to a very considerable sum.

The Approach of Spring.

Signs are not wanting even at this early period of the year that the time is drawing near when landscape and other out-door photographers will be able to sally forth once more on picture-making bent, with more bodily comfort than the recent cold, dark days have made possible. The afternoons are perceptibly lengthening, and the frequent spells of sunshine should be eagerly taken advantage of by the ever-increasing army of camera users who are not adverse to tramping across sodden fields and along muddy roads in search of picturesque landscape "bits" that at this time of year are surprisingly unlike anything of the kind obtainable in the autumn or at any other time of year. In those parts of the country where King Frost has laid his hand, much that is beautiful to the eye can be secured on every side, from the carefully-composed winter scenes or representation of hoar-frost to snap-shots of skating parties. In the warmer districts where the rainfall has been heavy, he who would portray and make pictures of marshy stretches with reflecting pools—present at no other time of year; desolate wastes of mud flats or dreary though picturesque woodland views with gaunt tree-trunks and bare branches and masses of fallen and decaying leaves that the winter winds have heaped around the roots, will find the present probably the best time of the year for this purpose. Fine cloud and atmospheric effects and sunsets, too, are much in evidence during February and

March, and these should be secured as often as the opportunity presents itself, for future use. Orthochromatic plates will find ample scope in the portrayal of these late winter and early spring subjects, for although there is little of the charm of colour present that appears in the more florid summer landscape the presence of dead bracken and other vegetation varying in tint from the palest of yellow to the deepest ruddy brown will frequently call for the use of a dark yellow screen.

THE SLACK SEASON.

PERHAPS no business demands more alertness and adaptability to environment than does photography from those who follow it. Success depends fully as much on such qualities as these as it does on the quality of the work produced, as is constantly being demonstrated. It is no uncommon thing to find a man doing poor work and making money while another not far off, maybe, does good work at a small profit. The commercial instinct being often lacking where there is love of the work for its own sake, such men are often exploited by others who know how to turn to good account the abilities they lack themselves. Many businesses now languishing could be made profitable concerns, if the proprietors were alive to the situation, instead of taking it for granted that what answered yesterday will do to-day and to-morrow. Then when business is bad his first thought is how to get more sitters, when often all that he need do is to make the most of those he has. A line that does not receive its share of attention is the tactful introduction of enlargements, and other forms of the photograph. Perhaps the photographer is not a good salesman and has no one capable; yet if the persons undertaking it will use their wits, and cultivate tact, they will find the faculty grow. Let the photographer used to a cabinet and c.d.v. business regard his orders for cabinets as a peg to hang an order for an enlargement on, carefully studying the taste of each customer, and having taken the order for an enlargement, let him sell a frame for it; a big difference in profits will result. We mentioned tact; it is the secret of success in this department. Much harm may be done by a too pushful receptionist on commission, who perhaps secures the order and offends the customer. It is very necessary, too, to give careful attention to the get-up of special lines. A departure from the conventional groove will secure many good orders which would otherwise be refused.

Oliver Sarony, of Scarborough, who was a good business man and an excellent photographer, made a feature of oil paintings. He had a large gallery containing portraits of celebrities, and a likely customer on leaving the studio was shown round the gallery, and finally into a small ante-chamber, where to his astonishment a large portrait of himself was thrown on the screen by means of a lantern, a transparency having been made in the meantime. That was in the early days of dry plates, and was exceptional enterprise for that period.

It will often happen that during the busy season there is not time to make the best of each customer, but in a residential district this can be made up in the slack season. A book should be kept, in which is entered the names of customers who are likely to order, with a note as to their tastes. Then when things are quiet a call can be made on one pretext or another, and the subject judiciously introduced; if properly done, this has none of the appearance of canvassing, and slack seasons have been converted into profitable times in this way.

Seaside photographers cannot do this, but they very commonly neglect their opportunities during the season, however. We have known many orders secured through

the post. In all this much depends on the ability of the operator. Undoubtedly his first aim must be a pleasing likeness. It may be technically and artistically excellent, but if it fails in expression it is useless. A very imperfect picture photographically will be preferred in which the photographer has secured the expression which is liked and recognised.

In endeavouring to push business, the photographer doing with a good-class connection should beware of anything that may result in loss of prestige. We have in mind the case of one who had a high-class clientèle, and who, by an unlucky inspiration, announced that he would

take sitters at half-price on a certain day in each week. That brought him ninety and one hundred sitters a day, but before long he had to charge the reduced prices at all times, and never recovered his former position.

As a rule, also, it is weak policy to do enlargements "on spec." in the hope of the customer buying. The photographer is at his customer's mercy in the transaction, and it creates the impression that he is hard up for business. Moreover, curiosity and imagination come into play when a customer is properly handled by a skilful receptionist, but are lacking when the customer sees the work completed.

A NEW LIGHT FOR PHOTOGRAPHY.

III.

The Deficiency of Red Rays.

MANY suggestions have been made for supplying the missing red rays in the light, a suitably fluorescing glass tube or glass jacket for the tube being one promising idea. Paweck, in Vienna, has proposed the introduction into the tube of amalgams—e.g., of mercury and potassium, whereby red lines would be introduced into the spectrum. It has further been noted that if too much current is passed by the lamp a good deal of red showed up in the spectrum.

It has been suggested that a red glass should be put in front of the light to modify it—a rather absurd idea, considering there is no red present in the light. The red glass would appear as grey or black glass, and would act as such, cutting off the light altogether if the colour was very dense. For the same reason colour filters in the camera would be useless. Ruby incandescent lamps have, however, been introduced in the vicinity of the tubes, and found to supply the proportion of red rays required. Ordinary incandescent lamps have also been found to tone the illumination owing to the yellow rays they emit. The most practical way, and the one which the Cooper-Hewitt Co. have adopted for toning the illumination in the case of their studio apparatus, is to have a blind of a very light transparent silk dyed with a pinkish fluorescent dye. This takes away the glare, and introduces an appreciable amount of red into the light. The exposure can be made with the blind down, in which case the time is increased, or the blind may only be drawn over during focussing and posing the sitter. It may be mentioned that the light produces no fatigue to the eye, even if looked at directly, and therefore does not distress the sitter even when placed close.

Diffusion of the Light.

The light is also perfectly steady and noiseless. It is extremely diffuse, and the great extent of the luminous surface does away with the glare and contrast of shadows cast by lamps of small light-giving surface. The modelling of features in portraiture is well rounded, and the necessity for retouching is, if anything, lessened. The hair of sitters is rendered more natural, and there is an absence of excessively deep shadows in the dress.

One advantage of the light for portraiture is that the operator sees the image of the sitter brilliantly on the ground glass and in monochrome, having almost the effect of a platinum print, so that he is better able to judge how his result is likely to look when finally printed, instead of being misled by colour effects of the dress, complexion, etc.

Shortness of Exposures.

With regard to exposures, it has been found necessary to employ a shutter even when the lens is stopped down to F. 16, any tapping of the lens by hand being out of the question on account

of the extreme rapidity of the light. The mercury lamp is indeed more rapid than the best daylight obtained in portrait studios. With five tubes, unscreened by the blind, using an ordinary portrait lens, snapshot exposures can be made. With three tubes, unscreened, the exposure is about half a second; with five tubes, screened, one second; with three tubes, screened, three seconds.

A further notable fact concerning exposures is that a number of fully-exposed cinematograph films of stage groups have been obtained, using eight tubes all round, and placed as close as practicable to the subjects, the films running at 1,200 to 1,300 exposures per minute. A number of tableaux at the Coliseum have also been made with the light, 120 negatives being exposed in one day.

The Form of Studio Light.

In the form used for studio work, five of the mercury lamp tubes are mounted in a wooden frame measuring 5 ft. by 4½ ft., and hung in a sloping position near the ceiling or roof, thus forming an artificial "skylight." The frame can be hung at any angle and lowered at will. Each lamp is provided with a separate metal reflector, and works independently, so that only as many lamps as required need be used at one time, with a proportionate decrease in the current consumed. The "skylight" may be used for printing by having a framework to attach to it for supporting the printing frames.

The actual candle-power of the five lamps together, considered from an illuminating point of view, is 3,750, equivalent to over 115 32-c.p. incandescent lamps, but owing to the fact that the mercury lamp is so rich in actinic rays the effective illumination is far greater than would be obtained by an equal nominal candle-power from any other light.

For photographic interiors, the mercury light is an efficient substitute for flash-light, and without the many drawbacks of the latter. The Hewitt light does not produce the hard "stary" effect of flash-light, is under far better control, and involves no danger.

Process Lamps.

For process reproduction the lamp has come considerably into use in America, and is found very efficient. Two forms of the lamp mounted on floor-stands are offered for this purpose, one being started by the quick-break method and the other by tilting. The light is so diffuse that it will probably be found unnecessary to have two lamps—one on each side of the copyboard—except where very large subjects have to be lighted. It is found that a pair of Hewitt lamps taking eight ampères will do quicker and more satisfactory work than arc lamps taking 25 ampères. On 200 to 300 volts two sets of the Hewitt lamps may be run in series taking only three to three and a half ampères, and yet giving quicker results than even the enclosed arcs run in parallel, taking ten ampères each, or twenty ampères the pair.

Transparency and Enlarging Work.

For making bromide enlargements, lantern-slides, and transparencies, no condenser is required, nor could it, in fact, be used. Two 10-inch tubes are mounted in a reflecting-box, which is pivoted to a baseboard fixed to the wall, and the lamps are started by the tilting method. The negative is placed in a carrier in front of the box, with a ground glass interposed, and a bellows and projecting lens used as in a daylight enlarging camera. The illumination is very even over the entire surface, and furnishes an ideal light for quick-printing papers, whilst for lantern-slide work it is over three times faster than exposure to a northern sky.

Rapid Printing.

For printing, the lamp shows equally remarkable results. Two of the long lamp tubes are mounted in a frame, on each side of which are places for supporting seven 7 in. by 5 in. printing frames, so that fourteen prints may be made at once. As an example of the speed of printing, it may be stated that P.O.P. prints from an ordinary portrait negative are fully exposed in five minutes, and platinum prints with proportionate rapidity.

In carbon printing, for some unexplained reason—possibly the yellowness of the film obstructing the actinic rays—the light is somewhat slow, but for blue prints the light is from four to six times as efficient as arc lamps. Moreover, the form of the lamp adapts itself to the cylindrical copiers now so largely used.

Remarkable Economy.

With regard to the economy of the light compared with other forms of illumination, each lamp tube consumes one-third of a kilowatt per hour, or one-third of the Board of Trade unit on which all supply companies base their charges for current. Taking the price per unit at 6d., which is as high as is generally charged in this country, the price of running one tube will be 2d. per hour. The cost of running the printing lamp outfit will be 4d. per hour, and of the "skylight" outfit 10d. per hour when all the tubes are on. In the case of the photo-engravers' lamp, where two are run in series, the cost will only be 2d. per hour when the current is 6d. per unit; but as photo-engravers get very low rates, such as 2d., 3d., or 4d., the cost may be only

a little under or a little over one penny per hour per pair of lamps.

Use for General Lighting.

It may be added that the mercury light is coming largely into use in America for general lighting of workshops, offices, etc., the diffusion, absence of shadows, and the fact that it gives no fatigue to the eyes being great advantages, apart from the question of economy. Practically, it gives one candle-power of light for half a watt of energy, whilst a candle-power for four watts is the best value that can be obtained from good incandescent lamps. From an electrical as well as a photographic point of view, the mercury light is of extreme interest, and is undoubtedly a factor to be reckoned with in the immediate future.

Cost of Outfit.

In regard to cost of the outfit, it is at present more expensive than arc lamps, but when it is considered that there is no expense to be set off against cost of carbons and trimming, besides a great saving in cost of current, and, moreover, the prices include resistances and suitable fixings, the difference is not material. A single tube and its accessories cost about £10.

Postscriptum.

Since writing the foregoing, Major-General Waterhouse kindly writes to say that during his recent visit to America, going along Broadway in the evening, he saw the mercury lamps in more than one place being used for portrait photography, and, he believes, very successfully. A mercury arc quartz lamp was exhibited at the St. Louis Exhibition by W. C. Heraeus, of Hanau-a-M., but perhaps more for scientific work with ultra-violet rays. There must have been others (continues Major-General Waterhouse) in the electrical building, and probably a number were used in the grounds at night.

I have also received a communication from C. Orme Bastian taking exception to my remarks concerning his type of lamp. He states that he can make them as large and powerful as is necessary. Considerable improvements have been effected in the lamp since the Press were invited to inspect it nearly a year ago. Mr. Bastian invited me to call at his works to inspect the latest forms of his lamp, and what I saw is so interesting and promising that it deserves some further notes, which must be deferred until next week. WILLIAM GAMBLE.

BLISTERS ON BROMIDE PAPER.

DURING the cold weather considerable trouble has been caused by blisters in bromide paper, not only in large enlargements, in which they are very apt to appear, but also in small contact prints. I believe the large blisters in enlargements are caused by the handling of the large prints in the various operations of fixing and washing, especially when the prints are of large size, 20 by 16 and over, for in ordinary professional workrooms such prints are rather out of the ordinary routine, and the dishes, etc., are often not large enough to take such without folding over, and creases and bruises are almost unavoidable, especially when single-handed. Such creases are a prolific source of blisters; but the most annoying are those small blisters about the size of a small pea, covering nearly the whole of a small print. They do not appear until the washing after fixing, but they often entirely disappear on drying, and come up again when the prints are re-wetted for mounting. They will often again disappear on drying, but occasionally, in rolling down the print, some of the blisters break, and the print is spoilt. This kind of blister is very annoying when prints are toned by the "sulphide" method, as they not only increase in size and number, but often become stained yellow, apparently owing to the difficulty of washing out the various chemicals used in the process.

Just before Christmas, when working against time, one batch of paper showed large crops of these small blisters, and a great many prints were spoiled. It was curious that one batch of paper blistered, while others of the same make and brand did not show blisters at all, although developed, fixed, and washed at the same time and in the same solutions as those that were covered with blisters.

A Remedy.

This state of things would have been serious at any time, but just then it was simply maddening, as there was no time to get fresh paper and to make experiments with it. Fortunately I remembered, while cudgelling my brains for a remedy, that we were often troubled with the same kind of thing in the bygone days of albumen printing. The remedy in those days was to immerse the prints in methylated spirit as soon as they were fixed, and before washing at all. This same remedy was tried, and proved a complete success. The bromide prints were taken straight from the fixing-bath and placed in a dish containing methylated spirit, and allowed to remain for ten minutes, and then washed in the usual way. No blisters appeared in subsequent operations, even toning with sulphide. The spirit can be used over and over again, and put aside for further use,

out freshened up with a little new spirit when used again. The mixture of spirit and water formed when drying negatives or prints that are wanted quickly can be saved and used for the prevention of blisters. Although this method prevents the formation of blisters, I do not like it, for, apart from the cost (which is but trifling) and an additional operation (which is not a great deal of trouble), I have an idea that a bromide print dried, or treated with methylated spirit, never has the same brightness and clearness as those dried spontaneously, so I prefer a paper which does not blister. Why one batch of paper should blister and another of the same brand treated in the same way should not is a question I cannot answer.

Large Blisters.

It has been suggested that the large blisters, which some bromide prints show when toned with sulphide, are due to grease on the surface of the raw paper. This seems a very good explanation.

tion, and is probably the right one. But I do not think it applies in the case of the small blisters, which appear in a few minutes after the removal from the fixing-bath to the washing-dish. Neither does the difference in temperature of the different solutions explain it, as some prints from another batch of paper developed and fixed at the same time showed no blisters at all. The cause is probably some difference in the raw paper before coating.

We all know that difference of temperature causes blisters. Only last week carbon prints when removed from the warm developing water to cold alum solution were covered with minute blisters, but when the prints were put into warm alum solution no blisters appeared.

I would advise any one who is suddenly afflicted with blisters of the kind that appear in the washing after fixing to try the methylated spirit cure.

HAROLD BAKER.

THE CORRECT ADJUSTMENT OF HAND-CAMERA FITTINGS.

Nor so many years ago the professional photographer would scarcely have regarded the hand camera as a serious tool. All this, however, is now changed. The hand camera is in daily and hourly use for purposes which could not be successfully met by the employment of a stand. The professional, generally speaking, has enlarged his outlook, and now goes in for much work which was previously abandoned. Frequently work has to be done on the spur of the moment, and a stand camera, of course, becomes impossible. It would certainly seem wise, therefore, to devote a little attention to some likely sources of inaccuracy in various hand-camera fittings which, if not prevented, may seriously vitiate the worker's calculations, and possibly lead to failure. These remarks will also, no doubt, be of interest to the large body of amateurs who habitually pin their faith to a hand camera in preference to the stand variety.

When Fitting a Diaphragm Shutter.

In the first place, it is well worth while to carefully examine the shutter and diaphragms, from the standpoint of their practical performance as compared with that theoretically allotted to them. It is not intended to touch upon the question of shutter speeds, for it has become quite a commonplace that the actual speeds of a shutter may differ markedly from its reputed speeds, and any photographer can, for a few pence, have the point settled to his own satisfaction. We will simply offer the caution that testing from time to time is necessary, since mechanical shutters are by no means constant in action, even a slight variation in temperature often sufficing to alter the speeds. It would, therefore, appear to be good policy to invest in a simple shutter-testing apparatus, of which there are several on the market. It is, however, a more serious matter than this to which it is specially desired to draw attention. A large number of both hand and stand cameras are now fitted with between-lens shutters having an iris diaphragm. Now, where these shutters are sold with the lens, or properly fitted by a competent optician, there will be nothing wrong. Unfortunately it sometimes happens that the photographer purchases lens and shutter separately, or has the latter fitted to an existing lens by a dealer's assistant, whose sole idea of the conditions to be fulfilled is that the parts shall screw together comfortably.

Focal Length and Shutter Aperture.

The result is probably disastrous, for a most important point is, in this case, almost sure to be overlooked, namely, the value of the diaphragm apertures. The shutter with its iris diaphragm is, as a rule, intended for use with a lens of a certain

focal length, and the scale of apertures is engraved on that presumption. Take, for instance, a shutter designed for a lens of 5 in. focus, with a largest aperture of F. 8. This size of opening will, of course, measure $\frac{5}{8}$ in. in diameter. If, now, the same shutter were to be employed with a lens of 8 in. focus, it is obvious that, unless the diaphragm scale were altered, the unsuspecting photographer who imagines that he is giving an exposure at F. 8 is in reality stopping the lens down to F. 12.8 and wasting over fifty per cent. of the available rapidity. Even an alteration of the scale will not always suffice, for the largest opening of the diaphragm may still be smaller than desirable. No account has been taken of the difference often existing between the effective aperture and the diameter of the diaphragm, which may be ignored as not affecting the present argument.

Test the Working Aperture.

The foregoing is a remarkably insidious error, extremely likely to occur, and infallibly leading to a large number of under-exposed and spoilt negatives. In a case which lately came under the writer's notice a well-known worker had for years been using a hand camera fitted with a high-grade lens at F. 6.3, but handicapped by a diaphragm shutter which reduced the largest aperture to something under F. 8. Evidently, the photographer will be well advised to test his diaphragm openings by a few simple measurements, unless both shutter and lens are obtained together under circumstances which preclude the possibility of error.

The Direct-Vision Finder.

In regard to finders it is strange that the advantages of this description of finder are so little recognised, since it forms by far the most practical and convenient appliance for the purpose. The kind referred to consists of a light rectangular wire frame having an opening the same size as the plate. This is arranged to fix on the rising front or on the lens, while a small circular peep-hole or sight is adjusted on the upper portion of the camera back. If this is correctly done, the arrangement enables the worker to see, immediately, the exact view included on the plate, right side up and of full size. Another advantage of this pattern of finder is that the actual picture is seen, not an image or representation of it; so that, especially in the case of figures or moving objects, the photographer is far better able to choose the best moment of exposure.

The Advantage of Two Finders.

In spite of its many good points, we seldom see this kind of finder fitted to hand cameras. Possibly one obstacle which mili-

tates against its adoption is its lesser portability, as compared with the smaller patterns. This objection is, in practice, more imaginary than real, and the device might easily be designed to fold compactly away when not in use. More serious is the necessity of raising the camera to the level of the eyes, when photographing figures, etc., at close quarters. The few occasions when it is desired to hold the apparatus at a low level may be anticipated by having the camera fitted in addition with the ordinary type of finder.

The Focussing Scale.

After what has been said, it would seem almost superfluous to recommend an examination of the focussing scale, if one is attached to the camera. And yet this is by no means so unnecessary as might be thought. It is not denied for a moment that every effort has probably been made by the manufacturer to ensure the accuracy of the scale, and that, in fact, it will be absolutely reliable if purchased with the lens as originally fitted. Tastes, however, differ with regard to lenses, and one customer may perhaps require the removal of an existing lens in favour of another which he prefers. This being the case, it may very well happen that a standard pattern of hand camera remains in stock, fitted with a different lens to that supplied by the maker. If this is of the same focal length as that for

which the focussing scale was graduated, well and good; if not it may mean many spoilt negatives before it dawns on the purchaser that a new scale is required. A very amusing instance may be quoted which occurred quite recently. A photographer purchasing a popular pattern of focal plane camera, desiring the removal of the rapid rectilinear lens with which it is usually sold, and the substitution of a world-renowned anastigmat at treble the cost. Unluckily it escaped the notice of both vendor and purchaser that while one lens was of five inches focus the other was of six inches, and the consequences, when the camera came to be used with the unaltered focussing scale, involved much unjustifiable abuse of the lens maker.

It will have been noticed that no fault has been found with the actual construction of hand cameras. This is only as it should be, for if the photographer is willing to pay a reasonable price he will very rarely find anything to complain of in this respect, since the manufacture of hand cameras has now reached a pitch of excellence and exactness which reflects the highest credit on those concerned. The only difficulties likely to occur are, as has been pointed out, rather due to the incorrect conjunction of fittings not adapted to each other than to any flaw or defect of workmanship; and in nine cases out of ten are avoidable by a little thought at the time of purchase.

A. LOCKETT.

SUPPLEMENTARY LENSES.

THE use of supplementary or additional lenses has become fairly common with hand cameras of the fixed focus type, and they are extremely useful, as they enable work to be tackled which would otherwise be quite beyond the scope of this type of camera. There is an equally wide field of usefulness for them, also, in conjunction with the ordinary focussing camera, and they deserve more attention in this direction than is usually paid to them. To many, however, they are practically an unknown quantity, and to others the subject seems hedged round with difficulties because their action is not fully grasped. The subject has also, quite unnecessarily, been complicated with mathematical calculations and formulæ, which, whilst extremely interesting to the theorist who thinks in logarithms and talks in cosines, is in many cases actually unintelligible to the man who uses a lens. There is not the slightest need for the subject to be complicated by such considerations, because the moment it becomes necessary to heed the refinements of mathematical calculations, a supplementary lens, in the sense that we are now using the word, is an impossibility, as will be seen later on.

To Lengthen or Shorten Focus.

The purpose of a supplementary lens may be either to lengthen or shorten the focus of the camera lens, or, to put it in another way, a supplementary lens will enable the angle included by a lens to be altered at will. To shorten the focus, a convex or positive lens must be used, and to increase the focus a concave or negative lens is required; but as these lenses must be chosen with some regard to the camera, it would possibly be as well to consider their use first with a fixed focus, and secondly with a focussing camera.

Fixed Focus.

It is, of course, a well-known fact that with a fixed focus camera the nearest point in focus is dependent, *ceteris paribus*, on the stop aperture; therefore, if we have a lens of a given focus, we are absolutely precluded from obtaining a sharp reproduction of an object which is nearer to the lens than a given point,

which said point is closer to the camera the smaller the aperture used; but there is a limit to the smallness of the aperture even in copying, and still more so in outdoor work. It is in such cases, therefore, that the supplementary lens is useful; because the lens being fixed at its equivalent focus from the sensitive plate, it can only give a sharp image of such objects as emit parallel rays. In this, then, lies the whole secret of the choice of a supplementary lens with a fixed focus camera. It must be of such a focus as to transmit to the camera lens parallel rays, and as this only occurs when an object is at the equivalent focus of a lens, it is obvious that focal length of a supplementary lens that shall give a sharp image of a near object at a given distance must be equal to that distance. Thus, if we wish to obtain a sharp image of an object at three feet from a fixed focus camera, we must use a supplementary lens of 3 ft. focus.

It will at once be obvious that the only supplementary lenses that can be used with a fixed focus camera must be positive lenses. With a focussing camera, however, it may be desirable not only to occasionally shorten, but also to lengthen the focus, and we then have other methods to consider, but as we have already pointed out, the calculations are extremely simple, and can be computed by the very simple processes of multiplication and division.

Calculations.

Of course, to the man with a battery of lenses the present notes are quite superfluous, but there are many who, only possessing, say, two lenses, may on occasions feel the necessity of having subsidiary help, and yet be loth to purchase an extra lens, which there may be occasion to use practically only once or twice a year. A special job may arise for which a lens of extremely short focus must be used, or, of course, on the other hand, one in which a long focus lens is required, and in fact, a telephoto lens will be the most satisfactory. Let us first consider, then, the case of a short focus lens being required. What we want to know is the focus of a supplementary lens that must be used to produce the required focus,

and, using the well-known rule, we obtain the following very simple calculation:—

$$\text{Required focus} = \frac{\text{actual focus} \times \text{supplementary lens focus}}{\text{actual focus} + \text{supplementary lens focus}}$$

and ascribing to these the values of 6 and 9 respectively we get

$$6 = \frac{9 \times f}{9 + f}$$

and thence

$$\begin{aligned} 54 + 6f &= 9f \\ 54 &= 9f - 6f \\ 54 &= 3f \\ \therefore f &= 18 \end{aligned}$$

which is the focus of the supplementary lens required. But simple as this is, we may put it in another way thus: Multiply the required focus by the actual focus, and divide by the difference between the same, then we get:—

$$\begin{aligned} 6 \times 9 &= 54 \\ 9 - 6 &= 3 \\ 54 \div 3 &= 18 \end{aligned}$$

When it is required to lengthen the focus we know that we must use negative lenses, so all we have to do is to insert the minus sign.

If we have a supplementary lens of known focus, and wish to know what focus will result when it is combined with the camera lens, we use the old rule of multiplying the foci together and dividing by their sum, so that if, as in the above case, we have a camera lens of 9 in. focus and a supplementary lens of 18 in. focus, we get:—

$$9 \times 18 \div 9 + 18 = 6$$

If the supplementary lens is a negative or concave, we again use precisely the same formula, only with the insertion of the minus or negative sign, thus:—

$$9 \times -18 \div 9 + (-18) = -162 \div -9 = 18$$

These calculations are so simple that they are within the capabilities of all, but the formulae are not correct. The error lies in the fact that we have totally ignored the distance of

separation; but as this distance of separation must be measured from the nodal points of the supplementary lens and the camera lens, and to the average worker these are absolutely unknown points, we have totally ignored them.

For the construction of a makeshift telephoto lens a negative lens should be chosen of about half the focus of the camera lens, and the distance of separation must always be greater than the difference between their foci, but may of course be varied considerably outside this limit.

The Choice of the Supplementary.

The next point to consider is the position of the supplementary lens, and putting on one side altogether the theoretically correct position, it may be placed before, behind, or between the lenses of a doublet, or in front of or behind a single lens. It is really a matter of indifference, though it is most convenient to fit them in the lens hood. Far more important than this is the form of the lens and its correct centring. The best form is the meniscus; next to that the plano-convex or concave. We have hitherto suggested that these supplementary lenses should be considered merely as makeshifts, and if looked upon in this light ordinary spectacle lenses may be used, but the working of their surfaces and the centring is so inferior that they may seriously impair the definition and even upset the corrections of the lens with which they are used, but as this may be to some extent cured by the use of small stops, it will suffice to draw attention to the point, and recommend that if the supplementary lens is to be considered as a permanent part of the outfit, then it should be adapted by an optician, who will supply an optically worked lens.

The only other point to which we need draw attention is the question of alteration of ratio aperture, for if we reduce the focal length and keep the aperture constant, then the ratio aperture must be increased, and as this can be so easily calculated it is unnecessary to dwell longer upon it, only pointing out that this applies only to cases in which a focussing camera is used, for if a fixed focus be used, then there is no alteration of focus, and the ratio aperture is the same.

THE WEEK IN HISTORY.

Fox-Talbot and Development.

On February 19, 1841, Fox-Talbot wrote a description of an experiment which he had made five months before. The experiment was the development of a latent image on his sensitive paper. The description occurs in a letter to "The Literary Gazette," and was published also in "The Philosophical Magazine" for 1841, page 90. That Talbot should have waited so long before announcing his result is, of course, explained by the fact that he was taking out a patent for this process. This he did, as I have already noted, on February 8, and he therefore felt at liberty to disclose in part the advances he had made. But he did not publish a full description of the process until June 10, by which time presumably, the patent had been sealed. His letter of February 19 runs as follows:—"One day last September I had been trying pieces of sensitive paper prepared in different ways in the camera obscura, allowing them to remain there only for a short time with the view of finding out which was the most sensitive. One of these papers was taken out and examined by candlelight. There was little or nothing to be seen upon it, and I left it lying on a table in a dark room. Returning some time after I took up the paper, and was very much surprised to see upon it a distinct picture. I was certain there was nothing of the kind when I had looked at it before, and therefore (magic apart) the only conclusion that could be drawn was that the picture had unexpectedly developed itself

by a spontaneous action. Fortunately, I had recollected the particular way in which this sheet of paper had been prepared, and was therefore enabled immediately to repeat the experiment. The paper, as before, when taken out of the camera, presented hardly anything visible; but this time, instead of leaving it, I continued to observe it by candlelight, and had soon the satisfaction of seeing a picture begin to appear, and all details of it came out one after the other.

Talbot afterwards stated (in "A History and Handbook of Photography," by G. Tissandier) that September 20 and 21, 1840, were the days on which he made these observations.

Sir John Herschel.

I have already referred to the work of Sir John F. W. Herschel, and we shall see later how he originated, independently of Talbot, a process which was like Talbot's in all respects save that he fixed his prints in hyposulphite of soda. That process he described to the Royal Society about three weeks after Talbot read his paper on February 21, 1839 (see below). Herschel continued his photographic experiments, and on February 20, 1840, communicated to the Royal Society a long paper which he entitled "On the Chemical Action of the Rays of the Solar Spectrum on Preparations of Silver and Other Substances, both Metallic and Non-Metallic, and on Some Photographic Processes." This paper, which appears on page 1 of the "Phil-

sophical Transactions for 1840," describes more than one method which has since come into general use.

Bleaching with Mercury.

For example, he examines the bleaching action of a solution of mercuric chloride or corrosive sublimate. "This," he writes, "at once and completely obliterates the picture, reducing it to the state of perfectly white paper, on which the nicest examination (if the process be perfectly executed) can detect no trace, and in which it may be used for any other purpose, as drawing, writing, etc., being completely insensible to light. Nevertheless, the picture, though invisible, is only dormant, and may be instantly revived over its face by merely brushing it over with a solution of a neutral hyposulphite, after which it remains as insensible as before to the action of light. And thus it may be successively obliterated and revived as often as we please. It hardly requires mention that the property in question furnishes a means of painting in mezzotints (i.e., in commencing on white paper, and working in the lights), as also a mode of secret writing and variety of similar applications."

It is easy to see how intensification has evolved from the substitution of other blackening reagents for the hyposulphite in the above method.

Herschel's Aim at Emulsions in 1840.

Reading further in this paper, it is curious to note how Herschel's first efforts were directed towards obtaining a liquid or emulsion which, "by a single application, whether by dipping or brushing over," should impart sensitiveness to his paper. Had he been experimenting with silver chloride instead of with the nitrate, photography might have leapt at one bound to the position which it reached in the eighties by slow and tortuous evolution. Writes Herschel: "The presence of organic matter having been considered by some late chemists an essential condition for the blackening of the nitrate of silver, I was induced to try, in the first instance, a variety of mixtures of such organic soluble compounds as would not precipitate that salt." But he met with no success in these researches although he went the length—I say "length," for obvious reasons—of extracting alkaline urates for the experiments from a boa constrictor in his possession!

Spectrum Sensitiveness.

The chief subject of this paper, however, is the action of the spectrum on sensitive compounds, and its absorption by liquids. Though we date the era of modern orthochromatism from Vogel in 1873, it is well to remind ourselves that Herschel used the spectrum, as a means of photographic investigation, in these very earliest days, and that the modification of the sensitive surface to render it impressive of rays of different refrangibility was one of the facts which he evidently kept clearly before him.

Photogenic Drawings—The First Published Process of Permanent Photography.

When Talbot read his paper of January 31 to the Royal Society ("The Week in History, January 27"), he dwelt in eloquent terms upon the power and wonder of his process, how it outstripped the artist's pencil in speed, and was correct to a hair's-breadth in its delineations, but of the process itself he said nothing at all. His second paper of February 21 was entirely technical, and is important as describing the first published process for obtaining a permanent photographic print. The original in Talbot's handwriting and scored with the marks of some editorial pen, is still preserved in the archives of the Royal Society.

The communication explains how to prepare the paper and how to fix the images. For the first, Talbot dips a good writing paper into a weak solution of common salt, wiping it dry, he applies silver nitrate solution to one surface, and dries the paper by the fire. He finds that if the salt solution exceeds a certain strength, the sensitiveness of the paper suffers. He finds also that after a week or two the sensitiveness of the paper is greatly reduced, but can be restored by application of the

silver nitrate. In other words, he finds the need of excess of silver nitrate, but does not attribute sensitiveness to that fact alone, but rather, as was shown last week, to its effect in producing a "perfect chloride."

The First Fixing Process.

He tried solvents of silver chloride as fixing agents, but he met with no success, no doubt because the darkened chloride also dissolved to a large extent in his fixing bath. Then he turns to a curious process. He uses iodide of potassium or chloride of sodium so as to produce an iodide or chloride of silver which is unalterable in light. He exhibits a copy of lace fixed by iodide five years before. "But my usual method of fixing," he proceeds, "is different from this, and somewhat simpler, or, at least, requiring less nicety. It consists in immersing the picture in a strong solution of common salt, and then wiping off the superfluous moisture and drying it. It is sufficiently singular that the same substance which is so useful in giving sensibility to the paper should also be capable under other circumstances of destroying it, but such is, nevertheless, the fact.

"Now, if the picture which has been washed and dried is placed in the sun, the white parts colour themselves of a pale lilac tint, after which they become insensible. Numerous experiments have shown to me that the depth of this lilac tint varies according to the quantity of salt used, relatively to the quantity of silver. By properly adjusting these, the images may, if desired, be retained of an absolute whiteness. I find that I have omitted to mention that those preserved by iodine are always of a very pale primrose colour, which has the extraordinary and very remarkable property of turning to a full gaudy yellow whenever it is exposed to the heat of a fire, and recovering the former colour again when it is cold."

HISTORIUS.

Photo-Mechanical Notes.

Zinc for the Enameline Process.

IN regard to Mr. Pigg's note last week on the perishing of zinc under heat, it will be noted that he does not venture on any explanation. The phenomenon has been ascribed to the fact that zinc expands on heating, but on cooling does not assume its original size. This would account for the more open structure shown in the photo-micrograph of the heated zinc. But the fact that zinc "perishes" at a high temperature is no reason why anyone should discard it for half-tone work, as the enameline process can be worked with it perfectly, provided certain precautions are taken.

The first is, a thin glue solution containing chromic acid; the second is, to use a hardening bath for the resist before burning in; and the third is, to burn in only very lightly, so that the enamel is only burned to a light straw colour. Under these circumstances we have known zinc to be etched, fine-etched, and then to stand an edition of 200,000 without in the least disturbing the enamel. A good enamel solution consists of:—

Fish glue	10 oz.
Water	30 oz.
Ammonium bichromate	2 oz.
Chromic acid	½ oz.
Ammonia (.880)	½ oz.

The chromic acid must be dissolved in some of the water and added drop by drop while stirring after the glue, water, and bichromate have been well mixed; finally the ammonia is added. The hardening bath consists of:—

Water	50 oz.
Methylated spirit	5 oz.
Ammonium bichromate	3 oz.
Chromic acid	½ oz.

The plate, after development, dyeing, and well washing, is laid

in this for from one to five minutes. It is best to "spot" plates that are to be lightly burned in, before burning in, as afterwards it is difficult to see any minute defects. After etching, plates can be easily painted out for fine-etching if magnesium carbonate is first rubbed in.

Process in India.

Major-General Waterhouse delivered a lecture at the Bolt Court School of Photo-Engraving and Lithography, Fleet Street, E.C., on the 9th inst., in which he dealt with the precautions and difficulties involved in the reproduction work directed by him for many years in the office of the Surveyor-General of India. Since his return to Europe in 1897 there have been changes in the methods adopted by the Government Process Staff, but parts of the paper which we are enabled to quote should prove of service to photo-engravers and others who may take positions in the East.

Wet Collodion in Hot Climates.

"The negatives for photo-zincography," said General Waterhouse, "have always been taken by the wet collodion process. Though slow, and presenting a good many inconveniences in working, it is more reliable, much cheaper to work on the large scale, and at the same time gives better and clearer results than gelatine plates. Most of the plates are only used once for printing the transfers; then cleaned off and the glasses used again. Thus dry plates become very wasteful in comparison when used in large numbers. For special work, chiefly half-tone of small size for heliogravure, dry plates are used with advantage.

"In a hot country like India there is a good deal of difficulty in working wet plates. For a great part of the year in Calcutta the temperature in the glass-house would probably be over 100 deg. F., in the day time even up to about 118 deg. F., and not much less in the dark rooms, so that many special precautions have to be taken. In the first place the silver bath should not be too strong; the standard strength was about 7 per cent., or 35 grains per ounce, and the bath must be kept sufficiently acid with nitric acid, to prevent fog, without thinning the image too much. We always used it in flat trays, but care must be taken not to allow the bath to become over rich in iodine, which it readily does if not kept up to strength. Baths also require pretty frequent sunning.

"The collodion used was made up in the office, from a mixture of pyroxyline and Schering's celloidine, iodised with the iodides of cadmium and ammonium, with some bromide of cadmium and a little iodine, and it contained a considerable proportion of alcohol, which was necessary in coating large plates; usually equal parts ether and alcohol were used for the mixed collodion and iodised.

"In hot weather the plates were very liable to dry during exposure, and it was necessary to pack them well with wet blotting paper while in the dark slides.

"The ordinary iron-developer was used with a large proportion of alcohol and acetic acid, to ensure the ready flow of the solution over the plate. The developer contained about 5 per cent. of ferrous sulphate, and 2½ per cent. each of alcohol and glacial acetic acid. The development was not carried too far, and if the lines appeared at all veiled a solution of iodine in iodide of potassium was applied and quickly washed off again. The plates were then fixed. As a rule the plates were not varnished, but to prevent peeling they were coated with a solution of gelatine about 4 per cent."

Direct Photo-zincography without a Camera.

For the reproduction of line drawings, maps, etc., it was usual at one time to employ the transfer process of photo-zincography, but in consequence of the coarseness of the lines, from spreading in transfer, a direct process was employed, the details of which were given by Major-General Waterhouse as follows:—"The plate is coated with a mixture of fish-glue, gelatine, and bichromate of ammonium, ex-

posed under a tracing, and then washed carefully to remove the soluble glue from the lines. When fully developed the lines appear sharp and distinct in clear zinc. Before development the plate may be stained with an aniline dye like a process block, to render the progress of development clearer. The plate is then inked up with a hard resinous ink thinned with turpentine, and applied either with a roller or by rubbing over the plate with a pad. The hardened glue on the ground is then removed by the immersion of the plate in a bath of very weak hydrochloric acid, which softens the glue without attacking the zinc, and enables it to be removed from the ground by rubbing with a piece of flannel. The last traces of glue are removed by rubbing the plate with carbonate of magnesia moistened with water. The plate is then dried, cleaned, touched up, if necessary, and can then be etched with nutgalls and gum as usual, and printed from. The process has many advantages in increased sharpness and freedom from distortion as well as in cheapness compared with camera work, but it requires special drawings."

Some notes by General Waterhouse on the climatic conditions of India as affecting photographic work and workers must stand over until next week.

Half-tones in Lithography.

In application of half-tones to lithography a patent (No. 10,855, 1904) has been granted to F. W. Sears, Berhampore, Wellington, New Zealand, for the process which is described in detail in the specification, but is sufficiently evident from the two claims:—(1) In the manufacture of half-tone engravings for lithography and other printing, the use of a half-tone positive with pure high lights produced by photographing through a screen the negative obtained by photographing the matter. (2) The improved process for making half-tone engravings for use in lithography and other printing, such process consisting in first photographing the desired matter, then photographing the negative thus obtained through a screen so as to produce a half-tone positive with pure high lights, and then printing from such positive (if for an intaglio) on to a metal plate or stone in the usual manner, or from such positive obtaining a contact negative and then printing from such negative on to zinc or aluminium sheets or stone.

It is difficult to see where the novelty comes in, since it is the common practice, in making intaglio half-tones to work from an ordinary negative and make a screen positive, this has been done probably for the past ten years, and is, if we mistake not, the subject of an old patent of Mr. Max Levy, and a recent one of Mr. Cameron Swan. And if it is correct, as Mr. Newton stated in an article published in the *BRITISH JOURNAL OF PHOTOGRAPHY* of January 20th, viz., that the using of screen positives to make half-tone negatives from has been in use since 1903 in London, there does not seem much novelty in the second part of the claim.

PHOTO-MECHANICAL PATENTS.

Application for Patent.

MATRICES.—No. 2,238. "Process for the manufacture of matrices for the galvano-plastic reproduction of printing blocks." Gustav Fischer, 6, Bream's Buildings, Chancery Lane, London.

SIR JOHN CASS Technical Institute.—On Tuesday last the fourth of a series of popular lectures was given at this institute by Dr. Charles A. Kohn, the principal, on the "Chemistry of Photography." Dealing more especially with the chemistry of the photographic film, the lecturer traced the gradual development of photography from the daguerreotype to the artistic productions of the present day. The composition of the film of the modern dry plate was carefully explained by means of numerous experiments, which included the actual making of a dry plate.

THE ROYAL PHOTOGRAPHIC SOCIETY.

The New President.

MAJOR-GENERAL WATERHOUSE, who was elected on Tuesday last to the Presidency of the Royal Photographic Society, has been occupied with practical and scientific photography for practically the whole of his life. In the years 1861 to 1862, when an officer of the Bengal Artillery, he was deputed to photograph the native tribes in Central India, and, in 1866 was transferred to the Bengal Staff Corps, on appointment to the charge of the photographic operations in the office of the Surveyor-General of India, a position which he occupied until 1897. During this period many improvements and innovations in reproduction processes were worked out under his direction. Photo-zincography, photo-collotype, and photographic engraving were the processes which chiefly benefited by these investigations, which

[Zambra.

MAJOR-GENERAL J. WATERHOUSE

Elected President of the Royal Photographic Society,
February 14th, 1905.

led also to the waxed-sand method of heliogravure. In 1871 he was deputed under Colonel (now Lieut.-General) J. F. Tennant, R.E., C.I.E., to assist in photographing the total eclipse of December 11, at Dodabetta, in the Nilgherry Hills, and again, in 1874, to take charge of the photographic observations of the transit of Venus (December 8), at Roorkee. In 1875, he had charge of the Indian expedition to observe the total solar eclipse of April 6, at Camorta, in the Nicobar Islands, on which occasion his attention was first turned to the action of colour-sensitisers by Dr. Vogel.

General Waterhouse was the first, in 1875, to experiment with eosine as a colour sensitiser, and to publish its action on the sensitiveness to yellow of silver haloid salts. This observation was followed by a long series of researches on colour sensitisers for gelatine plates

for which he was awarded the Progress Medal of the Royal Photographic Society in 1890. In the same year he investigated the reversing action of thiocarbamides in an alkaline developer, and pointed out its possible applications in photo-engraving. Since his return to Europe, in 1897, General Waterhouse has investigated the sensitiveness to light of silver and other metals, and has published a number of researches into the early history of the camera obscura, the tele-photo lens, and the photo-sensitiveness of silver salts, besides many other contributions to the "Photographic Journal."

During the years 1898-1900 he acted as Honorary Secretary of the Royal Photographic Society, and his election to the Presidency is a fitting recognition of services which have been ungrudgingly rendered to the Society on all occasions.

Exhibition.

THE Photographic Society of India held recently a "salon" at its club rooms in Calcutta, and, if we may believe a newspaper report, the collection includes specimens of photography in bromide, platino-type carbon, and "gum-bicarbonate" processes. The Society has our sympathies in the manner of its reporting in the lay Press, where it is also stated that one "photo stands out as one of the most unique in the whole collection." But the exhibition appears to have brought together a miscellaneous collection of photographs of considerable interest. Professional work was represented chiefly by Messrs. Johnston and Hoffmann, who obtained a gold medal for their "Interior of the Zenana Jasmine Tower, Agra," and a silver medal for a portrait of Mrs. Lucia King as Lady Macbeth. Messrs. Herzog and Higgins were awarded a silver medal for a picture entitled "Delhi Durbar." There were altogether thirty-seven exhibitors who sent in about 172 subjects, which were divided into seven classes. In the first class for a collection of photographs, the Society's gold medal was awarded to Mr. George Wilson for his set of four pictures in Bartolozzi-red carbon prints representing studies of children. The silver medal fell to Mr. F. M. Muriel for his studies in trees on platinotype. The process used in these photographs were singularly adapted to the subjects. In Class 2, for portraits, Mrs. Seaton was awarded the silver medal for a child study entitled "First Steps." This was a charming little subject and admirably composed. The bronze medal fell to Dr. Pearse for a portrait. This was a very characteristic study and showed careful work. In the third class, landscapes, marine, and architectural subjects, the gold medal was awarded to Kumar, Raja of Bobbili, for a marine study in bromide. One interesting exhibit was an enlargement of a "Panorama of Lhasa," by Messrs. Johnston and Hoffmann, from a negative by Mr. Claude White.

FORTHCOMING EXHIBITIONS.

February 15-March 15.—International Exhibition Artistic Photographs, Vienna. Hon. Secretary, Dr. Reiniger, Camera Club, Largerplatz No. 3, Vienna III., 3.

February 16-18.—Norwich and District Photographic Society. Hon. Secretary, E. Peake, Rydal House, Earlham Road, Norwich.

February 21-March 7.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

February 24-March 4.—Northampton Photographic Society. Entries close February 14; for pictures, February 17. Hon. Secretary, E. J. Felce, 83, Adam's Avenue, Northampton.

February 25-March 4.—Birmingham Photographic Society. Hon. Secretary, Lewis Lloyd, Norwich Union Chambers, Congress Street, Birmingham.

February 25-March 11.—Edinburgh Photographic Society. Entries close February 11; for pictures, February 15. Hon. Secretary, J. S. McCulloch, 3A, North Saint David Street, Edinburgh.

March 4-11.—South London Photographic Society. Hon. Secretary, H. Creighton Beckett, 44, Edith Road, Peckham, S.E.
 March 14-17.—Brentford Photographic Society. Hon. Secretary, F. H. Read, Ferndale, Clifden Road, Brentford.

March 16-30.—International Photographic Exhibition, Earl's Court. The Organising Managers, 119-125, Finsbury Pavement, London, E.C.

March 20-25.—The Cripple Gate Photographic Society. Hon. Secretary, John B. Parnham.

March 27-April 1.—Leicester and Leicestershire Photographic Society. Entries close on March 20, 1905. Secretary, R. Warden Harvey, Oriental Cafe, Market Place, Leicester.

March 30-April 3.—Chiswick Camera Club. H. Gentry, 39, Fairfax Road, Chiswick.

April.—International Exhibition, Genoa. Sec. Gen., Piazza Fontane Marose 18, Genoa.

April 3-15.—Photographic Society of Ireland. Hon. Secretary, R. Benson, 35, Molesworth Street, Dublin.

April 7-May 8.—International Artistic Exhibition, Berlin. Director, Herr Franz Goerke, Maassenstrasse 32, Berlin, W.

May 1-31.—International Exhibition of Photographic Picture Postcards, concurrently with the 10th Salon. M. le Secrétaire Général du Photo Club de Paris, 44, Rue des Mathurins, Paris.

May 10 to June 19.—Salon of the Photo Club de Paris. Entries close March 1, and pictures must arrive by April 10. Secretary, Paul Bourgeois, 44, Rue des Mathurins, Paris.

June.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

March 31.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Limited, Ilford, E.

September.—Kodak. £400 in prizes for results on Kodak products. Kodak, Ltd., 57-61, Clerkenwell Road, London, E.C.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents were made between January 30 and February 4, 1905:—

COLOUR PHOTOGRAPHY.—No. 1,906. "Improvements relating to preparing colour-sensitive plates or films for a process of colour photography." W. N. Lascelles Davidson, 55, Chancery Lane, London.

VAPOUR LAMPS.—No. 2,004. "Improvements in electric vapour lamps or enclosed arc lamps." Charles Orme Bastian and George Calvert, Birkbeck Bank Chambers, Chancery Lane, London.

DRYING PLATES OR FILMS.—No. 2,082. "Improvements in apparatus for drying photographic plates or films." A. J. Chapman, 107, Mansfield Street, Kingsland Road, London.

WASHING AND DRYING PLATES, ETC.—No. 2,083. "Improvements in apparatus for washing and drying photographic plates or films." J. Hazell and A. J. Chapman, 107, Mansfield Street, London.

CAMERAS.—No. 2,093. "Improvements in photographic cameras." W. J. Lancaster, 24, Temple Row, Birmingham.

MAGAZINE HOLDERS.—No. 2,120. "Improvements in magazine holders for photographic plates and films." J. F. Spong, 18, Southampton Buildings, Chancery Lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

These specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

GELATINE.—No. 1,477, 1904. "In making gelatine and glue from bones, the use of oxidising salts is claimed as an improvement in the maceration of the bones and in the after clarification and bleaching of the gelatine liquor. Permanganates and peroxides are among the substances used." Otto Schneider, 44, Burgschmietstrasse, Nürnberg, Germany.

FLASH POWDERS.—No. 27,267, 1904. "For smokeless and non-

explosive flash powders, an alum or sulphate of copper is the novel ingredient patented in conjunction with the metals, magnesium, or aluminium. These flash powders are mixed with oxides or carbonates of alkaline earth metals, or with glass powder to produce a slow-burning 'time' powder. Typical formulæ are:—
 1. Flash powder.—Magnesium, 10 parts (or magnesium, 2 parts; aluminium, 2 parts); chrome alum, 10 parts. For 'time' powder.—Magnesium, 100 parts (or magnesium, 80 parts; aluminium, 20 parts); chrome alum or copper sulphate, 100 parts; lime oxide, carbonate, or glass, 20 parts." W. P. Thompson and Co., 322, High Holborn, W.C.; for Dr. G. Krebs, Offenbach-on-Main, Germany.

FLASH POWDERS.—No. 27,268, 1904. "For the manufacture of a non-explosive smokeless powder mixtures of metallic aluminium or magnesium (or both) are made with silicic acid, boric acid, nitrates of alkali, and alkali earth metals; with amorphous phosphorus or silica for quicker combustion, and with carbonates of alkali or alkaline earths, silicic acid, etc., for slower combustion. By the additions of oxides and carbonates of the alkalies or alkaline earths respectively, the amorphous phosphorus and the nitrates may be prevented from burning with the evolution of a large quantity of smoke which contains phosphorus acid and phosphoretted hydrogen, which are injurious to health; this fact has been mentioned in American Patent No. 528,515. The addition of suitable oxides of carbonates prevents the development of smoke and of noxious fumes. It may be mentioned that silicic acid and boric acid are used in flashlight powders, as, for instance, in the powder patented in Germany under No. 101,528, but this powder contains neither amorphous phosphorus nor nitrates, and therefore the silicic acid and boric acid serve a quite different purpose. Typical powders.—1. Flash: Magnesium, 100 parts (or half of which may be replaced by aluminium); alkaline nitrate, 200 parts; amorphous phosphorus, 5 parts; magnesium silicate, or carbonate, glass powder, or the like, 5 parts. The lights may be coloured by additions of certain salts." W. P. Thompson and Co., 322, High Holborn, London, W.C., for Dr. G. Krebs, Offenbach-on-Main, Germany.

FLASH POWDERS.—No. 27,465, 1904. "For the manufacture of powders which are non-explosive and produce very little smoke protection is claimed for mixtures of magnesium or aluminium, with compounds of the heavy metals, which can act as carriers of oxygen. Suitable compounds for this purpose are oxides, carbonates, and sulphates of iron, lead, and copper, alone or in combination. A typical formula is:—Magnesium, 100 parts; aluminium, 50 parts; oxide of iron, 30 parts; copper carbonate, 20 parts; magnesium sulphate, 5 parts." Hans Lückte, Paul Arndt, and Ernest Leopold Löwengard, 8, Zellstrasse, Wandsbek, Germany.

Mr. VICTOR TAYLOR, hon. secretary of the Photographic and Pictorial Survey and Record of Essex, writes to say that the photographic and pictorial survey of the county has been begun by the Essex Field Club. At a meeting called for the purpose on November 24 he was asked to take the matter in hand, and the necessary rules and by-laws having been agreed to, the whole thing has now been in working order for a fortnight past. The officials will be happy to receive contributions to the funds of the survey and also photographs and prints for the permanent collection. Lord Rayleigh has given his patronage to the work, Mr. F. W. Rudler (president of the Essex Field Club) is the president, and Mr. W. C. Waller, of Loughton, treasurer. The secretary states that he will be glad to correspond with societies of kindred nature, archaeological societies, and photographic societies, and with anyone willing to give assistance in the work of the survey.

New Apparatus, &c.

Feculose, a New Mountant. Made by W. Wotherspoon, Glenfield Starch Works, Paisley.

It is conceivable that there are many photographers who will question the need of new mountants. They have used starch as long as they can remember, and they have found starch good enough for them. We ourselves have often insisted on the desirability of starch as an adhesive, its chemical and photographic purity, the ready preparation of the paste in a perfectly sweet condition, and the tenacity with which it holds the mounted print. But we do not therefore contend that it satisfies every requirement of the photographer. *Autres temps, autres mœurs*, and now that emulsion papers are so largely in use, and now that the glossy print equally with the heavy toned paper are included in the output of many photographers, it is discovered that there are qualities of starch paste which are undesirable, notably its penetration of the paper and its tendency to cockle thin mounts. Moreover, the amateur worker seems to find endless difficulties in the proper making of the mountant. For these reasons there is much to be said in favour of the various other adhesives which have been placed in photographers' hands within recent years. The latest of them is Feculose, a fine, white dry powder, which apparently can be kept unchanged for any time under proper conditions. On testing it for acidity, we find it to be perfectly neutral, in which condition the prepared paste can be kept by addition of a little preservative. Our own preference is to make fresh each day, but if an antiseptic is to be added we should advise thymol in the proportion of about 2 grains per oz. weight of the paste. The paste is made as follows:—The powder is thoroughly mixed with four or five times its weight of water, and heated for ten minutes, preferably in the inner compartment of a double vessel of the "porringer" type, with water boiling in the outer vessel. If made in an ordinary saucepan, it is allowed to simmer for fifteen minutes without coming actually to the boil.

The mountant which results is a thin, glutinous medium of great tenacity, which is applied with the greatest ease, and excellently suits, so far as we can discover, the varied prints which the photographer is called upon to handle. Prices and samples of Feculose are obtainable from the makers at Paisley, or from the London house, 19, Laurence Pountney Lane, E.C.

A Combined Plate Rack and Print Dryer. Sold by John J. Griffin and Sons, Limited, Sardinia Street, Lincoln's Inn Fields, London, W.C.

A system of three bars hinged to a support, which is screwed to

the wall is all the mechanism of this useful piece of apparatus. Each bar is fitted with brass clips by which the prints, twenty-four in all, are attached, whilst the topmost bar is slotted in places for the reception of negatives. The rack costs 3s.

A New Studio Camera, made by the Camera Construction Co., Eagle Works, Durham Grove, Hackney, London, N.E.

We have recently inspected a camera, the makers of which aim at meeting the wants of a photographer who cannot afford a high price,

but must nevertheless have an instrument with which he can do all ordinary work, and which is capable of withstanding wear and tear. In designing a camera on these lines the Camera Construction Co. have adopted a very solid construction; the instrument is for the studio only. The whole of the woodwork is mahogany, and the brass fittings are of the ample dimensions which ensure convenient handling. The novel feature of the camera is the repeating back, which is $9\frac{1}{2}$ by

$9\frac{1}{2}$ inches, and accommodates two half plates, a whole plate, or smaller sizes. It permits the duplicating or triplicating exposures on one or more plates, and is set for this purpose beforehand so that the operator has only to push the slide forward, and has no need to withdraw his attention from the sitter. The camera has double swing back, rising front, loose lens panel, and a total extension of 30 inches. Its price in the $9\frac{1}{2}$ by $9\frac{1}{2}$ size is £6 10s.

It is proposed to form a photographic society in connection with the Willesden Polytechnic, Priory Park Road, Kilburn. A preliminary meeting was held at the Polytechnic on Monday last.

The catalogue of Mr. William Hume, 1, Lothian Street, Edinburgh, reaches us in its latest edition, and it need scarcely be said that its thirty-two pages are occupied with specifications and illustrations of enlargers and accessories in great variety. Mr. Hume will send the list free, and it is certainly one which anyone contemplating an enlarging outfit, great or small, will be well advised to procure.

A MENACED National Beauty Spot.—It is an ancient tradition at Bristol that native-born citizens always sleep with one eye open. But they must have assuredly shut both eyes and their minds as well to allow the beautiful Avon valley to be vandalised by hideous quarrying for road-making materials. A local correspondent of the "Globe" says that this ruthless work is now being carried on at express speed, and neither the Corporation nor the Board of Trade shows the least disposition to save one of the finest beauty-spots in the whole kingdom from becoming a ghastly eyesore. It is just as if Richmond were to have remained passive when the glorious view from the terrace was threatened by building operations on the other side of the river. But the desecration is much less pardonable at the Avon than that would be. There are lofty cliffs on both sides, those on the right bank being bare and almost perpendicular, while on the left Leigh Woods clothe the slopes from ridge to foot. There is no prettier bit of sylvan scenery in England, and, viewed from Clifton Downs across the river, is picturesque charm is surpassing. This, then, is the lovely spot marked down by the civic Huns and Goths for the quarryman's dynamite performances. It is not even that the quarrying must needs be carried out on the face of the wooded cliffs; the ugly scooping could be done on the reverse side, and so be imperceptible from the opposite point of view.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Feb.	Name of Society.	Subject.
17.....	G.E.R. Mechanics' Institution	<i>Natural History Photography.</i> Mr. G. T. Harris.
17.....	Aberdeen Photo. Association	<i>Interiors of Public Buildings.</i> Mr. A. Walker, I.L.D.
17.....	Watford Photographic Society	<i>Watkins' Method of Time Development.</i> Dr. C. H. Hall.
20.....	Hastings Camera Club	<i>The Cathedral of Winchester.</i> Mr. S. G. Kimber.
20.....	Southampton Camera Club	Lantern Slide Competition.
20.....	South London Photo. Society	<i>Marine Photography.</i> Mr. F. J. Mortimer.
20.....	Bowes Pk. and Dis. Ph. Soc.	Exhibition, Reception of Pictures.
21.....	Royal Photographic Society	<i>A West Country Minister.</i> Mr. E. W. Harvey Piper.
21.....	Glasgow Southern Ph. Assn.	Opening of the Fourth Annual Open Exhibition.
21.....	Nelson Photographic Society	<i>Magnesium and Candlelight Photography.</i> Demonstrated. Mr. F. W. Waker.
21.....	Rodley and Dis. Photo. Soc.	<i>Wanderings Over the West Riding.</i> Mr. Holmes.
21.....	Brenford Photo. Society	<i>Enlarging.</i> Discussion opened by Mr. J. G. Wright.
21.....	Birmingham Photo. Society	<i>A Large Aperture.</i> Mr. F. E. Wardall.
21.....	Thornton Heath Photo. Society	<i>Bronze Work.</i> Mr. J. H. Avery.
21.....	Balgownie and Dis. Ph. Assn.	Annual General Meeting.
21.....	Hove Camera Club	<i>The Cathedral of Winchester.</i> Mr. S. G. Kimber.
21.....	Everton Camera Club	<i>A Visit to the United States.</i> Mr. W. S. Johnson.
22.....	Windsor Camera Club	<i>Lantern Slide Making.</i> Mr. E. Oetzmann.
22.....	G.E.R. Mechanics' Institution	<i>Photomicrography of Starches.</i> Demonstrated. Mr. J. H. B. Jenkins, F.C.S.
22.....	Cricklewood Photo. Society	<i>Through Normandy and Brittany.</i> A series of Slides lent by Messrs. T. Cook & Sons, Ltd.
22.....	Photographic Club	<i>A Paper by Mr. P. R. Salmon, F.R.P.S.</i>
22.....	North Middlesex Photo. Soc.	<i>The Elements of Pictorial Photography.</i> Mr. H. Snowden Ward.
23.....	Hull Photographic Society	<i>Gun-Bichromate.</i> Demonstrated. Mr. Thomas Heaps.
23.....	Rugby Photographic Society	<i>Photo Lithography.</i> Mr. B. B. Dickinson, M.A.
23.....	Optical Society	Annual Meeting.
23.....	Southport Scientific Societies	<i>British Sea Snails.</i> Illustrated. Mr. E. Kimbault Diblin.
23.....	Liverpool Amateur Ph. Assn.	<i>The Dee from Arran to Hülbre.</i> Dr. J. W. Ellis.
23.....	Camera Club	<i>Recent and the Recent Discoveries in the Forum.</i> Mr. W. A. Casson.
23.....	Leigh Photographic Society	<i>Lantern Slide Making by Reduction.</i> Dr. H. S. Hall.
23.....	London and Prov. Photo. Assn.	<i>Orthochromatic Photography.</i> Mr. A. J. Bull.
23.....	L.C.C. Sch. of Ph.-Engraving	<i>How Paper is Made.</i> Mr. R. W. Sindall, F.C.S.
23.....	Richmond Camera Club	<i>Lantern Lecture on Pompei.</i> Mr. C. H. Davis.
23 and 24	Bowes Pk. and Dis. Ph. Soc.	Exhibition.

ROYAL PHOTOGRAPHIC SOCIETY.

THE annual general meeting was held on Tuesday last, the 14th inst., Major-General J. Waterhouse in the chair. The report of the Council for the year 1904 was taken as read. This and the balance sheet for the year had been in the hands of members for some days, and the discussion which followed had for its subject the items in these documents. It is stated in the report that the scientific photographs collected by the society for exhibition at St. Louis will be exhibited at Russell Square on their return from America. The membership has increased by 21 during the year, a figure which includes 84 enrolments and 57 resignations. The affiliation now numbers 148 societies within its ranks. In regard to finance the cost of the exhibition was £37 less than in previous years, but there was a total falling off in the receipts of £133, made up of £50 admission, £37 advertisements, and £46 space charges. The profit on the exhibition was £35. The society has been at increased office charges of £55, and the cost of the "Journal" has been £65 more than in the previous year. Two house exhibitions have been held by M. Robert Demachy and Mrs. G. A. Barton respectively. The library has grown considerably, and the new catalogue is promised for the end of March. The research laboratory, advocated by Sir Wm.

Abney, has received financial support to the amount of £133 19s. 6d., but the Council appeal to the members for the further help which is necessary to establish the scheme.

Considerable discussion, formal and informal, of the report took place, chiefly in reference to finances, the annual exhibition, and the withdrawal of medals from the pictorial section. A number of suggestions and recommendations were put forward, but the whole proceedings were somewhat desultory in character, and as they dealt chiefly with the internal working of the Society no useful purpose would be served in reporting them. Some sharp criticism was indulged in by some members of the action of the late Council in peremptorily withdrawing the medals from the annual exhibition, but the feeling appeared to be more against the way in which the step had been taken than against the action itself.

The New Officers.

The scrutineers of the ballot reported the election of the following officers:—

President, Major-General J. Waterhouse, I.A.; vice-presidents, Sir W. de W. Abney, K.C.B., F.R.S., the Right Honourable the Earl of Crawford, K.T., F.R.S., J. C. S. Mummery, Sir J. W. Swan, M.A., F.R.S.

Treasurer, John Sterry.

Ordinary members of the Council: A. W. W. Bartlett, H. W. Bennett, P. H. Emerson, B.A., Douglas English, B.A., T. E. Freshwater, F.R.M.S., Sir W. J. Herschel, J. A. Hodges, F. Hollyer, F. Ince, Dr. G. Lindsay Johnson, M.A., M.D., Rev. F. C. Lambert, M.A., Furley Lewis, Ernest Marriage, C. H. Oakden, E. Sanger Shepherd, C. W. Somerville, John Spiller, F.I.C., F.C.S., W. Thomas, H. Snowden Ward, B. Gay Wilkinson.

Judges—Technical and Scientific Section: T. Bolas, F.I.C., F.C.S., Douglas English, B.A., T. E. Freshwater, F.R.M.S., Chapman Jones, F.I.C., F.C.S., E. Sanger Shepherd, E. J. Wall, Major-General J. Waterhouse, I.A.

A portrait of Major-General Waterhouse, with some notes on his contributions to photography, appears on another page.

PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

A MEETING of the General Committee was held at 51, Baker Street, W., on Friday, February 10, 1905. Present: Messrs. Alfred Ellis, Wm. Grove, Martin Jacolette, E. C. Elliott, S. H. Fry, H. Edmonds Hull, A. Mackie, Lang Sims, R. Fellows Willson, Wm. Gill (Colchester), P. Lankester (Tunbridge Wells), and H. C. Spink (Brighton). Mr. Alfred Ellis in the chair.

The assistant secretary intimated that in accordance with the decision of the last meeting an arrangement had been made with THE BRITISH JOURNAL OF PHOTOGRAPHY to insert notices of the assistants' certificates scheme at the heading of the Situations Vacant and Wanted columns of that paper. He reported that the parties to the arbitration case decided at the last meeting had expressed their satisfaction with the result, and that the case had been settled in accordance with the finding. He also reported a similar case between a member and a firm of postcard printers, which had been settled by correspondence. In both the above cases, which were between members on the one side and non-members on the other, the non-members had since joined the Association.

A letter was read from a member complaining that a neighbouring photographer whose name did not appear in this year's "Handbook" advertised himself as a member of the P.P.A. The Hon. Secretary was instructed in the subject.

A letter was read from Mr. Warrington, hon. secretary of the Liverpool branch, referring to a recent severe illness. The hon. secretary was instructed to express the Committee's sympathy and good wishes.

A rather complicated matter respecting the price-cutting of bromide postcards, in which a charge against a member of the Committee had been made was successfully refuted, was discussed and dealt with. A point of considerable importance to photographers was involved, but it was deemed advisable not to publish the particulars.

It was reported that up to date forty-eight replies only had been received to the inquiry made of the members as to their views on the subject of a Benevolent Fund. Twenty members disapproved, and twenty-eight approved, promising subscriptions in the aggregate to the amount of £19 6s. 6d. annually. It was agreed to deal with the matter finally at the next Committee meeting.

A long discussion took place upon the proposal of Mr. S. H. Fry at the annual general meeting that provision should be made in the constitution of the Association for the admission of assistants who hold certificates to Associate membership, or to some similar position with regard to the Association. This matter also was adjourned to the next meeting.

Matters connected with the assistants' certificates scheme were discussed, and details with regard to the examination of applicants' papers were dealt with. Messrs. Alfred Ellis, Ernest C. Elliott, and Wm. Grove were appointed to form a Board of Examiners for operating, printing, and retouching.

In view of the frequency of cases being submitted to the Association to deal with as arbitrators, it was decided that, to avoid the delay and other disadvantages involved in bringing the cases before a Committee meeting, it was advisable to appoint a Board of Arbitration, and five members of Committee were thereupon appointed.

Before separating, the members of Committee present decided to hold an informal dinner, at which it was agreed that any other members of the Association who might like to be present would be welcome. The arrangements, when made, will be announced.

THE OPTICAL SOCIETY.

MEETING held Monday, February 13, at 20, Hanover Square, London, W.—A paper was read by Mr. W. E. Phillips on "Measurement of Absorption in Tinted Glasses," in which he described the use of the Flicker photometer for this purpose, the method being drawn up for application to the Simmance Abady photometer of the Flicker type. The principle of the photometer, he explained, was the bringing of two surfaces, illuminated by two sources of light, alternately into view at a certain periodicity. If unequally illuminated, a throbbing or flicker effect will be noticed. This effect may be due to the pupil of the eye failing to keep time with the rapid change of intensity of illumination of the two screens. The fact that two surfaces, each illuminated by light of a different colour, can be measured for intensity in this way is ascribed to the difference in the senses of lightness and colour, the former being much keener and quicker in action than the latter. Professor Herring had stated his belief that the senses were different; one might be present without the other. In the Simmance Abady type of Flicker photometer light from the two sources is received upon a wheel of pure white material, which is rotated at a known and controllable speed by a clockwork motor. The periphery of the wheel is formed of two equal conical surfaces, and when it revolves the intersection of the two surfaces crosses the line of sight. The two surfaces are seen alternately on looking through an eyepiece. The photometer being placed between the two sources of light, so that they are at right angles to the line of sight and parallel with the axis of the wheel, the effect produced by each light is seen when the wheel rotates. The author employed a bench 2 metres in length when making the measurements. The illuminants were enclosed in blackened boxes with an aperture in the front. The first adjustment is made to equalise the illuminations of the unscreened lights, and then the glasses, the absorptions of which are to be measured,

are inserted, and a second reading taken. The most satisfactory source of light was found to be either an Argand burner for gas or a small glow-lamp with straight filaments, supplied with current from an accumulator.

LEEDS PHOTOGRAPHIC SOCIETY.

ON Tuesday evening, February 7, Mr. R. Stockdale, M.A., gave a demonstration on "The Carbon Process" before the above society. Mr. Stockdale recommended sensitising the tissue with a $2\frac{1}{2}$ per cent. or 3 per cent. solution of bichromate of potash. When making up the solution, add a piece of ammonium carbonate about the size of a walnut to a quart of potassium bichromate solution. This will keep the tissue in good condition for a longer time. The tissue was probably in best condition when three or four days old. A 5 per cent solution made the tissue more sensitive, and therefore suitable for denser and more contrasty negatives. The "Akuret" actinometer was economical and fairly easy to judge, and was recommended.

As transparency tissue contains more pigment, it was specially useful for making transparencies for enlarged negatives, or lantern slides from negatives which were rather dense and would not yield good results on ordinary lantern plates. The glass support needed no preparation, but should be scrupulously clean. A safe edge was always necessary, or frilling occurred. A sponge could be used to assist development, and also a camel-hair brush charged with hot water. The lecturer stated that the Rotary Co. had recently issued some carbon tissue on a transparent film for support. This was printed through the support, and so did not require transfer, and therefore yields direct and not reversed prints. These could be used direct or stripped if required. In this case no safe edge was needed, as there was no stripping of the support of the tissue prior to development. For certain classes of subjects this should be very convenient.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION. MEETING held February 9, at the White Swan, Tudor Street, Mr. R. Beckett in the Chair.

Mr. Snowden Ward gave a lecture on "Photography for the Press," taking as his text the advice: "Study the editor through his journal," and only submit work that is likely to suit that journal. Photographers, as a rule, only look at their own side of the question, forgetting that the editor has also to have an opinion. An editor cares little for technique, or pictorial quality, so long as the stuff is what he requires to fill his paper and illustrate his point. The whole lecture was interspersed with anecdotes well and wittily told, all of which illustrated in a lucid manner the various points raised. In the discussion, opened by Mr. Thomas, copyright was mentioned by the Chairman, and Mr. Mackie quickly put on his best judicial air, and, armed with "British Journal Almanac," was ready to expound the law. But time was short, and Mr. Snowden Ward said that he was glad to find that his first proposal to talk upon copyright would have been appreciated.

CROYDON CAMERA CLUB.

FEBRUARY 8.—The new pigment printing method, introduced by the Autotype Company, under the name of "Auto-Pastel," was demonstrated by Mr. Braham. As the process has already been described, and its working indicated in these columns, recapitulation is unnecessary; but one or two practical points, evolved from further experience, may usefully be mentioned.

Auto-Pastel, broadly speaking, may be said to have a strong family likeness to gum-bichromate, inasmuch as it is a direct printing method, without transfer, is susceptible to a large amount of control, and in skilful hands—as was illustrated by Mr. Braham—with good effect. The actual manipulation, however, differs—the image must be developed, or brought into being, by gentle abrasion, a broad

camel's hair brush being a satisfactory tool for the purpose; hot water is also a necessary adjunct. In another and rather important respect it also differs from "gum," for, given a reasonably accurate exposure (which should err on the side of over, rather than under), then purely mechanical development will in each case result in a straightforward representation of the negative, the sporting element of uncertainty, which characterises its prototype, being conspicuously absent. It must not, however, be assumed that in the case of normal development all the fine detail and gradations of the negative will be reproduced. The process is essentially one for broad and striking studies, as shadows are to a great extent massed, and detail subordinated; indeed, the lecturer expressly stated that it was not intended to supplant, or even rival, the carbon process; each had its sphere and its usefulness.

Mr. Braham showed a capital contrivance for developing, which would appear to be equally applicable for carbon work. It consisted of a rectangular wooden frame, on which coarse muslin was stretched, forming a sort of shallow tray; this was allowed to float in the hot-water tank, the print resting on the muslin, just underneath the surface of the water. The lecturer also described and showed how any part of the picture might be lightened in tone by repeated applications of the brush, other portions being, if necessary, held back by a reversal of the process; small high lights could be emphasised by means of cork, or paper stumps, and even trees, reflections in water, and so forth, indicated by their aid. When the print was dry, further artistic manipulations might be carried on with ink-erasers, and possibly with sand-paper, a jack plane, and a coarse file, though it must be admitted Mr. Braham did not suggest the use of the last three.

In answer to a question, Mr. Braham said that since the issue of their printed instructions it had been found that the paper worked even better with soft, harmonious negatives than with the fairly strong negatives previously recommended. An animated and appreciative discussion followed, which terminated with a hearty vote of thanks to Mr. Braham and the Autotype Company for bringing an interesting method of pigment printing before the members of the club.

HULL PHOTOGRAPHIC SOCIETY.

Mr. T. F. BROGDEN, of Scarborough, gave a lecture last week on "Hand-Camera Work." In the first place he said it was necessary to possess a suitable camera, lens, and shutter for the work it is intended to do. He used a hand-camera with Cooke $\frac{5}{8}$ in. lens and Unicum shutter, but recommended, where the pocket would allow of it, an F/4 lens and focal-plane shutter when it was practically possible, to be equal to everything which might turn up under all conditions—dull days and difficult subjects. He strongly emphasised the personal element in all work done, with simplicity of subject. Numerous examples were given, by lantern slides, where at the time of exposure only a certain portion was actually seen, but after development foreign matter was seen to be present, and here it was necessary to do away with that which spoils the original idea. The lecturer made these points very clear, showing how several of his "Royal" exhibits had received this treatment. With hand-camera work we were only allowed one exposure with any given subject, and so we must understand our instrument and plate, etc. Under-exposure should be avoided, for no developer would make good its defects. It was advisable to dilute the developer. The lecturer advised the use of a large stop always, and if circumstances were favourable he preferred to increase the speed of the shutter rather than stop down the lens. A little judicious over-exposure was always advisable.

Commercial & Legal Intelligence

At Bromley recently the magistrates investigated some extensive thefts of photographic apparatus. The stolen property was of the total value of nearly £30. The accused, against whom there were four separate charges, was Walter Ware, residing at Broom Hill, Orpington. He had not been regularly employed for some time past, and Mr. Richard Cartwright Davenport, the prosecutor, a tradesman of London Road, Bromley, had found him occasional employment. The prisoner took advantage of his visits to prosecutor's premises to rob him of goods in a wholesale manner, and then pledge them. The prisoner pleaded guilty, and was sentenced to six months' hard labour.

LAFAYETTE, LIMITED.—Last week the seventh ordinary general meeting of Lafayette's, Limited, was held in Dublin. Mr. S. S. McCormick, J.P., presided. Mr. Aug. Klingner read the report, which recommended a dividend of 14 per cent. for the half-year, making 10 per cent. for the year, and carrying forward £518 6s. 8d. which was unanimously adopted. Mr. William Fry, jun., in proposing the re-election of the retiring director (Mr. McCormick), congratulated the company on its flourishing condition. In the original prospectus the directors estimated the annual average profit at £6,600, but this balance-sheet showed they had made £7,985. Messrs. Stokes Bros. and Pim were re-elected auditors.

PHOTO AND ART PRINTING COMPANY, LIMITED.—Registered February 3, by A. L. Mason, 122, Victoria Street, S. W. Capital, £27,500, in £1 shares (7,500 Preference). Objects: To carry on the business of photographers, photographic and general printers, lithographers, artists, engravers, modellers, publishers, stationers, paper makers, chemists, booksellers, bookbinders, etc. No initial public issue. The first directors (to number not less than two nor more than five) are to be appointed by the signatories. Qualification (except first directors) £300. Remuneration (except directors acting as managers), £100 each per annum (chairman £150), and 10 per cent. of the surplus profits after a dividend of 6 per cent. has been paid on the Preference and Ordinary shares, divisible (maximum additional remuneration, £1,000). Registered office, 122, Victoria Street, S.W.

A SCORE for the Defendant.—At the Bolton County Court on Wednesday, before his Honour Judge J. K. Bradbury, Mr. W. Russell appeared on behalf of Mr. Taylor, photographer, Manchester Road, defendant in an action brought by Frederick Charles Morris, electrician, of 7, Mawdesley Street, to recover the cost of work done for defendant. Plaintiff in December, 1903, undertook to put an electrical installation in defendant's premises, to be used for the purpose of photography. He put in switches of 15 amperes in place of 20 amperes, which defendant alleged was required for the purpose of making the installation complete. Plaintiff contended there was no difference between the 15 and 20 amperes, that the installation was adequate, and that the work was satisfactory. He produced the certificate of an electrical engineer, which he said freed him from any further liability. On behalf of defendant it was submitted that plaintiff had failed to perform his contract, and that the amperage was not of the required capacity. Mr. Russell called three witnesses, and his Honour found a verdict for defendant, with costs.

ACTION Against an Enlarging Firm.—Before Sheriff Campbell Smith, in the Dundee Small Debt Court, last week, Miss Macleod sued Alf. Margard, trading as the Crown Art Co., for 30s., in lieu of wages. In course of cross-examination of the defender it was suggested that the business was carried on on the Tanqueray system, but his Lordship was not satisfied that the business was carried on in this way. The defender stated that the pursuer had been in his

employment for one week. Amongst other places she had visited Barrow-in-Furness, and had received a return ticket. It was understood, however, that she was to tour round that district for three months. After a few days, however, pursuer said she wanted to go home. Witness wanted to get her ticket in order to prevent her going home, and ultimately he got it. He thought he had a right to it, as pursuer had broken her engagement. Pursuer was paid 15s. for the week. In regard to the breaking of the engagement his Lordship held that defender was in the wrong, and granted the sum sued for with expenses.

At the Liverpool Bankruptcy Court on Thursday last, Alfred Stephen Leslie, who was described as a cinematograph exhibitor, living in Belmont Road, Liverpool, came up for his public examination. The liabilities were stated to be £616, and assets £44. The bankrupt said he got an appointment from a corporation as lanternist to attend lectures, and, later, he bought a bioscope for £36, which was part of some money he received under an aunt's will. With this he gave shows on his own account, but did not accumulate money by it. After that he made an arrangement with the proprietor of the Irving Theatre, Seacombe, and he had paid the proprietor £78 in connection with the original cost of taking the pictures and preparing the films. His engagement was for three weeks, and his share of the net profits came to £15 the first week, £6 for the second, and nothing for the third. The theatre proprietor was now returned as a creditor. Since 1893 he had been insolvent, and there had been nothing but writs and summonses all the time, which had cost him about £150 to ward off. In addition to his general impecuniosity, a serious and long illness in his own family had cost him at least £100 in doctor's bills, etc. The last 18 months he had been pledging his lanterns and other things, and there were now 40 creditors, out of a total of 128, who had got judgment against him. The examination was adjourned to March 9.

TORQUAY Photographer's Failure.—The first meeting of creditors and public examination in bankruptcy of Samuel James Porter, photographer, 4a, Strand, Torquay, was held at Exeter on Friday last. The gross liabilities were stated to be £2,476; expected to rank for dividend £622; assets £235; deficiency £386. The cause of failure alleged by debtor were depreciation of property, and being obliged to move his Torquay business, and heavy rental of Torquay business premises. The Official Receiver, in his printed observations, said:—"The debtor states that he commenced business at Ventnor, Isle of Wight, in 1890, with a capital of about £190. About seven years ago he opened a branch at Torquay, five years ago another at Paignton, and three years since at Exeter. He sold the Ventnor business about two years ago, the Paignton business in September last, and the Exeter business in November, 1903, the Torquay business being the only one now carried on by him. The fully-secured creditors include the bankers for £134 7s. 8d., who hold a guarantee, and the guarantor holds for security for that and his own debt of £54 6s. 9d., two bills for £135 given by the purchaser of the Exeter business, and six bills for £10 each given by the purchaser of the Paignton business. The last of these bills falls due in July, 1906. There are two fully-secured creditors for £900, holding first and second charges on a freehold house at Paignton. The partly-secured creditor for £710 holds a mortgage on a long leasehold house at Ventnor, of the estimated value of £550. The landlord of the Torquay business is a creditor for £180 balance of rent to Christmas last, of which he claims in full six months' rent, £112 10s., and as security for the remaining rent he holds a life policy worth about £15, and three bills amounting to £100, part of the purchase money of the Paignton business. The unsecured creditors for sums over £10 each include three for £194 for money lent, one for £15 for furniture, and the remaining creditors are all for goods supplied."

News and Notes.

A **GRAND PRIX** (highest award) has been conferred upon Messrs. Burroughs, Wellcome, and Co. for the pharmaceutical and other products exhibited by them at the Cape Town International Exhibition.

THE death is announced of Mr. Thomas Woods, of Birr, at the age of ninety. The deceased gentleman held the position of medical officer at the Birr Dispensary until a few months ago. He was an ardent cyclist and photographer, and practised both amusements within a few weeks of his death.

MESSRS. HEDINGHAM AND Co., Photographic Enlargers, etc., late of 15, Isledon Road, Holloway, N., write us that in consequence of their largely increasing business they have removed to more commodious premises situate at 5, Whitehall Parade, Archway Road, London, N.

At a meeting of the Hillsboro Society last week, Mr. C. H. L. Turner, representing the Rotary Photo Co., gave a demonstration on "Rotox" and "Rotograph" bromide and gaslight printing. He also showed the Rotary Co.'s specialities in carbon tissues, carbon stripping films, and the new patent stripping films for three-colour photography.

LAST Saturday at the Photo Art Club, Aberdeen, a lecture and demonstration on enlarging was given by Mr. D. Duff. The successful members in the "mouning" competition were: first, Mr. Stephen; second, Mr. Jarvis; and third, Mr. Dalgity. The judges, Messrs. Findlay and David, laid special emphasis on the skill and taste displayed in the prints taking first and second places.

PHOTOGRAPHIC Survey and Record of Surrey.—The annual meeting will be held in the Croydon Town Hall on March 11, at 5.45, when an address will be delivered by Viscount Middleton. The same evening an exhibition of some 1,300 prints will be opened, and will be on view on the following Monday, Tuesday, and Wednesday, from 3 to 5 and from 7 to 9 p.m.

LEEDS Photographic Society.—On Tuesday evening, February 21, Mr. Godfrey Bingley, the President of the Yorkshire Photographic Union, will lecture before this society on "Oxford and Cambridge." The annual conversazione, which was to have taken place on February 21, has been fixed for March 1 in the Philosophical Hall, Park Road.

MESSRS. BEAVAN AND SONS, Lowther Arcade, Carlisle, notify us that they have opened at the above address as a photographic dealers, and have in stock a good supply of plates, papers, etc., by all the leading makers, and a good dark room for amateurs. They also lend cameras (up to 15 x 12) out for hire by the day or longer—a convenience, we should think, to amateurs wanting to take large pictures. Mr. Beavan has been with Messrs. G. W. Wilson, Aberdeen, for over ten years, and will be pleased to place his experience at the disposal of his customers, who can obtain from him their copy of THE BRITISH JOURNAL OF PHOTOGRAPHY.

THE Sheffield Photographic Society held its monthly meeting on Tuesday night last, when an interesting lecture was given by Mr. Alex. Keighley on "Flower Photography." The lecturer was one of the first to make a special study of photographing flowers amidst their natural surroundings, and in this particular branch of photography he has excelled himself. The usual style of plucking the flowers, placing them in a stiff vase, and endeavouring to make them look natural was conspicuous by its absence. The lecturer conducted his audience through each month, showing beautiful examples of the flowers which were typical to the time of the year.

THE Bowes Park and District Photographic Society held their lecturette competition on Monday evening, February 6, at their headquarters, Unity Hall, Wood Green. Mr. A. J. Craston demonstrated his method of carbon printing, sensitising and developing

prints before the meeting. Mr. E. H. Young gave a humorous paper on "Economical Photography," showing how a photographic outfit, including camera, can be constructed for something less than one shilling. The resulting print he was reserving for the forthcoming exhibition. Mr. H. C. Bird gave a paper on "A Method of Controlling the Gradation of Bromide Prints." The result of the voting was: Mr. H. C. Bird, first; Mr. E. H. Young, second; Mr. A. J. Craston, third.

New Societies.—Another new photographic club is being inaugurated in Glasgow, and by a special arrangement with the local manager of the Kodak Company their rooms in Buchanan Street will be placed at the disposal of members of the club one evening each week. This will include the use of dark room, enlarging apparatus, and a reference library. The names of intending members are being received by Mr. Frank C. Petrie, interim hon. secretary, 4, Lorne Terrace, Maryhill. A society has also been formed recently in the east end of the city, "The Glasgow Eastern Co-operative Camera Club," and meetings are held every alternate Wednesday in Sword Street Hall. A syllabus has been arranged, and the secretary, John M. Hamilton, 85, Evelyn Street, Dennistoun, will be glad to receive additional names.

The President of the Royal Institute of British Architects, in his recent address to the students at the Institute, made some remarks which are well worth the attention of people who think for themselves on art questions. He uttered a warning against the popular habit of confusing archaeological interest and artistic value, and deprecated the common tendency to allow a mere sentimental consideration for picturesque antiquity to pervert æsthetic judgment. He declared that historical associations, by their appeal to a love of romance, are apt to give to old buildings a fictitious value in the eyes of the public, and to cause these buildings to be accepted as fine architectural examples, when they really lack those beauties of design which would justify them in being regarded as suitable subjects for study; and he argued, correctly enough, that this concession to sentiment was likely to have a bad effect upon both the taste of the modern architects and the quality of their art.

Stolen Goods.—At Taunton Police Court, last week, Arthur Harris, a respectable-looking young married man, who has been employed as a photographic printer at the establishment of Mr. Henry Montague Cooper, photographer, East Street, was charged with having stolen six photographic lenses and two cameras, of the value of £21, the property of his employer. The defendant pleaded guilty, and expressed his sorrow. He said he had had a good character, and was in his last place fourteen years. He had never committed an offence before, but he was pressed for money, and he pawned the articles for small amounts, hoping to be able to redeem them before they were missed. Mr. Cooper said that he had found the defendant a capable and attentive workman, and he did not wish to press the charge against him. It was very painful to him to take proceedings, and he asked the Bench, if possible, to deal with the defendant under the First Offenders' Act. The Mayor said the defendant had a great deal to be thankful for in that he had been in the employ of a gentleman who was so lenient towards him. The Bench would bind him over to come up for judgment if called upon within six months.

A New Photographic Accessory.—The latest development of the craze, so prevalent amongst a certain class, for imitating the ways of those moving in a different stratum of society has of late assumed the form of being photographed seated in a motor-car. A writer in the "Sun," commenting on this species of affectation, says:—"The people to whom these remarks refer do not own cars, and are never likely to do so, but their craving to be thought aristocratic leads them to fall a prey to the bait held out by a certain class of photographers. It costs considerably more, of course, to be depicted in

this way than in the ordinary style, because the car has to be hired by the photographer, and the services of an expert driver are necessary to coach the "gentleman how and where to place his hands," and generally to comport himself as if motor-driving were but an incident in his every-day life. No doubt the instructor performs his duties in this respect in a conscientious manner; but it is beyond his powers to impart to the temporary occupants of the car that air of complete indifference to their surroundings which nothing but constant association can secure. This is especially the case with the "ladies," who invariably wear a half-scared expression on their faces as if they were by no means sure that they are in altogether safe keeping, and not liable to be run away with by the car at any moment. Those photographers who turn their attention to this class of business do not advertise the fact. They simply make hints to those of their clients to whom they think the suggestion is likely to appeal. Should such be the case, an appointment is made for another day, and, instead of having their "picture taken" standing together arm in arm, or resting negligently against the immemorial "what-not," the customers relinquish all idea of being taken at the time, and return home to await the new appointment. The photographer provides everything, from the "fur" overcoat and gloves for the gentleman, to the veil and cloak for the lady, and the expert arranges the latter's veil and hat as if she were about to brave the fury of a fierce nor-easter. Later on the photo is enlarged, and framed, to excite the envy of the acquaintances of the persons portrayed, who are not aware what an age of shams we are living in.

The principal disadvantages of flashlight (said Mr. J. G. Everett in the course of a demonstration at the Royal Albert Institute, Windsor) are:—First, the quantity of smoke produced; second, the difficulty of spreading the light over a sufficiently large area to prevent the appearance of harsh shadows and hard contrasts in the negative. The remedy for the first of these difficulties is to use plates as rapid as possible and as large a stop as is admissible, and so reduce, as far as one can, the quantity of magnesium to be burnt. With reference to the second difficulty, the following points may be useful to remember: In blowing the spray of magnesium into a flame use a fairly wide tube and blow gently. This will give a large sheet of flame, and the shadows can be further softened by placing some kind of reflector, such as a mirror or a white sheet or card, in such a position that it will reflect the light upon those parts that would otherwise be in the shade. When the source of light is to be one of the explosive mixtures frequently used for the purpose the powder should be spread out before ignition so as to produce as large a flash as possible, and it is even better to use two flashes a little distance away from one another. It is necessary that the two flashes should take place simultaneously, as otherwise the second will show up the "start" which the sitter is almost certain to make when the first goes off. The most convenient method of firing these flashes is by means of electric fuses, and if the two fuses are both worked by the same switch the operator may depend upon his flashes taking place simultaneously. One frequently notices in portraits that have been taken by flashlight a peculiar startled expression about the eyes. The probable reason for this appearance is that the room was darkened just before taking the photograph. The darkening of the room causes the pupils of the sitter's eyes to expand to an extent which appears abnormal when seen by daylight, and it also causes the sitter to unconsciously strain his eyes in order to see what the operator is doing. It is quite unnecessary to darken the room when taking a flashlight photograph, as provided the light from the lamp used does not shine directly into the camera the lens could be left uncovered in an ordinary room for some little time without appreciably affecting the ultimate result. It is also advisable to place the flash somewhat above the sitter's head, as this will give the portrait a more natural appearance.

Correspondence.

- * * *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*
- * * *We do not undertake responsibility for the opinions expressed by our correspondents.*

BRENTFORD PHOTOGRAPHIC SOCIETY'S EXHIBITION.

To the Editors.

Gentlemen,—I beg to enclose you an entry form of the forthcoming Brentford Exhibition, and should esteem it a favour if you could find space in your next issue for a notice of the exhibition, drawing attention of probable exhibitors to the fact that pictures can be sent between the South London, Brentford and Cripplegate Exhibitions, free of carriage to the exhibition.

Also we are again having an open class, amongst others, for pictures (any subject) that have not been previously exhibited.

On a former occasion this class was a great success, and we feel sure it will again appeal to exhibitors, therefore our wish to make it as universally known as possible. Brentford being outside the London Postal District, exhibits in this class will not be debarred from selection at the Salon or R.P.S.—Yours in anticipation,

FRANK H. READ, Exhibition Secretary.

"Ferndale," Clifden Road, Brentford,

February 9, 1905.

ADVERTISEMENT.

To the Editors.

Gentlemen,—Your little hint of novel advertising, offered by our American Cousin, who hung the sign of "Time is Flying," etc., was the cause of racking our brains for a cheap advertisement of a like kind. We have hit it remarkably well, and daily the crowds gather around our windows with expectant faces, scanning each photograph with the hopes of recognition. The reason for the same is easily explained. A notice of reward of £20 has been printed in the ordinary form, which will be paid to the persons giving information that will lead to the conviction of the persons who entered our studio, on a specified date, and without cause or reason deliberately smashed our cameras. We have placed in the window a photograph of the parties concerned, which we trust will lead to their early identification.

Signed, etc.,

Needless to add the faces are those of a couple of well-known local comedians, taken as ugly as they can possibly be taken, with this notice written above:

"We are sorry, but our faces slipped."

People smile when they see the catch, and we know we are being cheaply advertised.—Yours faithfully,

ATHERTON AND Co.

5, St. Peter's Road, Great Yarmouth.

[We are interested in hearing the experience of our correspondents. Perhaps they, and others, may be glad to hear that a short series of articles on advertising, in regard to the business of a photographer, will commence in an early issue.—Eds.]

HONORARY PHOTOGRAPHERS.

To the Editors.

Gentlemen,—I have read with great interest the correspondence dealing with the "honorary photographer" scheme proposed by the proprietors of "Woman's Life," and I quite agree with the attitude taken by your correspondents. A similar scheme was inaugurated some time ago by another paper, and the following little incident—founded on fact—should give a clue to the "further remunerative business" likely to accrue to the photographer foolish enough to accept the office of "Honorary Photographer":—

Scene: A photographer's studio. Time 8 a.m.—Photographer discovered arranging things for day's work. He has no cares. He sings blithesomely. The sun shines ditto.

Enter Assistant.—"Morning, Sir. Going to be a fine day I think; lots of people out. This is the sort of weather to bring 'em in. By the way, I see you have been appointed 'Honorary Photographer' to the 'Weekly Thundermug.' I suppose you will soon be moving into a bigger shop?"

Hon. Phot.—"Er—ye—es, I suppose so."

9 a.m.

Enter stout lady and six offspring. The four eldest are budding hooligans, the youngest is in arms.

"'Ere we are at last. Now, mister, I 'av'nt had my phiz took for ten years come next Whit Monday, but my nevvie, what keeps the little paper shop off the Balls Pond Road, 'as 'ad a bundle of specimen copies of the 'Weekly Thundermug' sent 'im, so we've cut out the coupons what gets the photographs took at your shop, and 'ere's twenty-four of 'em. That's a photo for each of us, 'aint it, and two for little Willie? So look lively, guv'nor, and slip into it."

Hon. Phot.—"O lor!" (He slips into it.)

12 noon.

Hon. Phot. (surveying studio wrecked in places by the hooligans).—"Thank goodness that's over. Now, Tomkins, has anybody called?"

Assistant (breathlessly).—"Called! I should say so. There are nineteen servant girls, five errand boys, and a drunken navy out side now. They have all got 'Weekly Thundermug' coupons, and the navy has already had a fight with the postman and insulted two old ladies who came about a wedding group, and half-a-dozen other regular customers. He says he won't shift until he has had his three-p'orth of clock torture, if he's got to sleep here all night."

Hon. Phot.—"O lor! Dash! likewise blow! Here, go out and put the shutters up. Say I've gone abroad and won't be back for a month."

Assistant left struggling with drunken navy.

—Yours truly,

EX-HONORARY PHOTOGRAPHER.

A USEFUL ACCESSORY FOR THE TECHNICAL PHOTOGRAPHER.

To the Editors.

Gentlemen,—The technical photographer who is called upon to photograph all sorts of odd objects is often at a loss for a suitable background, particularly if he has to do the work away from his own studio, as is usually the case. The handiest thing I have found so far is a pair of boards, about 2 ft. square, hinged at the centre and with a leather strap screwed on at each end to serve as handles to carry the boards. The boards are covered on the inside with a good quality of black velvet, evenly glued on. Now if these boards be opened and one laid on a table with the other at right angles, we have both a base and a background for our object. Velvet

is recommended, because although a white background is more frequently required than a black one, yet if the board is made white it does not remain so very long, but soon becomes dirty and marked with handling and pin-holes, whereas the velvet will be as good as ever after much use if it is brushed occasionally. Then with a roll of new, uncreased white and grey paper the operator has three backgrounds at his command, neither of which will cause work on the negative, as is so often the case with extemporised backgrounds.—Yours faithfully,

TECHNICUS.

Answers to Correspondents.

* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.

* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.

* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.

* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

F. Henderson, 72, Queen's Road, Aberdeen. Photograph of Herbert and Janet Scott.

W. Eastoe, Castle Hill House, Caistor, Lincolnshire. Photograph of "The Walk," or "Beatched Farm," Bimbok, Lincolnshire.

Prior, 23, Edgcombe Place, Stoke, Devonport. Three Photographs of three of the Plymouth Celebrities, entitled, "Pennycross Bill," "Jubilee Bill," and "Fogey."

E. Hargreaves, Millom, Cumberland. Four Photographs of the Rev. Ivor G. Farrar, M.A.

Dunn, 38A, Brighton Road, Redhill, Surrey. Photograph of the Interior of the Mission Room, High Street, Redhill.

rs. M. Le Tourneux, 249, Regent Road, Salford. Photograph of the Rev. J. Hennessy.

T. Healey, Carfax Studio, Horsham, Sussex. Photographs of Dinner Meal, Dinner Parade, Dormitory, and Trades, before dinner, all at Christ's Hospital.

M., FREEZE, and several other querists will be answered next week.

LEVY, PARIS.—Thank you for the note.

E.—There is no benevolent association now in existence.

J. R. Y. K.—1. A. 2. A large aperture anastigmat and a telephoto attachment.

ARCH LIGHT.—We do not know the address, but care of Royal Institution, Albemarle Street, London, W., would probably find him.

J. SELLWOOD and F. LORD.—We cannot fall in with your suggestion, and if you wish to dispose of the apparatus you should advertise it.

CULLIFORD.—Your query has been handed to us by the printers.

Your easiest plan is to have the label drawn or printed and then make a negative, and you can then obtain as many pulls as you like on ordinary flat celluloid positive films or the thin.

ORY MINIATURES.—Would like to know of a house that supply plain ivory miniatures from negatives or prints.—A. B. C.

This work is undertaken by any of the trade printers, for whose addresses consult the advertisement columns.

REUTLINGER POSTCARDS.—Would like to know if Reutlinger postcard products are copyright in England. If so, who can I apply to for the right to reproduce?—A. B. C.

Yes, we believe they are all copyright, and that the same is vested in the Rotary Photographic Company, Union Street, Moorfields, E.C.

VISIBLE INK.—Can you give me through the columns of your valuable journal recipes for making an invisible ink that will keep, or name of book in which I can find same?—G. A.

The following formula is given in our ALMANAC:—Chloride of cobalt, 50 grs.; distilled water, 1 oz.; glycerine, 50 minims. Dissolve in the above order. This is invisible till warmed.

UBBER BALL.—I have a time and instantaneous shutter; the air has gone out of ball because of a small prick in the ball. How could I inflate it? Or, if necessary to have it repaired, please say who would put it right again?—SHUTTER.

It certainly is not worth while tinkering about with any mending dodge, considering that a new ball and tube can be

bought from the makers of the shutter, or any dealer, for fifteenpence.

PLATINUM-TONING ON C.C. PAPER.—In your article on above in issue of 27th ult. it is advised that oxalic acid be used, as being least open to objection. Would you kindly inform me the correct strength of acid to use and the quantity?—R. D.

The bath advised by Namias is:—Potass. chloroplatinite, 1 gm.; distilled water, 1,000 gm.; pure hydrochloric acid, 5 gm.; oxalic acid, 10 gm. The British weights are:—15 grs., 35 ounces, 80 grs., and 150 grs. The object of the hydrochloric acid is to convert the soluble silver salts into chloride, an advantage as regards pure whites.

ELIMINATION OF HYPO.—Will you kindly give me your opinion as to how long it is necessary to wash negatives to thoroughly eliminate all traces of hypo? I have heard various times mentioned by several different West-end operators. Of course, I refer to washing in an ordinary syphon tank. An operator who has photographed Royalty gives two hours; yet his master says one hour is ample. Another operator says thirty minutes. We have decided to abide by your opinion.—OXONTIAN.

Provided the negatives are fixed in a bath made alkaline, by the addition of one ounce of ammonia to 12 pints of hypo solution, for fifteen minutes, the whole of the hypo may be eliminated by thirty minutes' washing in a syphon tank.

HYPO ELIMINATORS.—I shall esteem it a favour if you will kindly inform me if you consider hypo eliminators work satisfactorily, as it would be a great boon to me if I could find some satisfactory method for considerably shortening the time required for washing prints after fixing in hypo. Will you also kindly recommend the eliminator you consider most satisfactory, and give the price of same and where obtainable?—G. A. D.

We must confess that we consider plain water the best hypo eliminator, and as all prints can be freed from hypo in one hour by repeated soaking in water and changing the same every ten minutes, the time involved is not much; still, the best of the chemical eliminators is potassium percarbonate, which can be obtained from nearly all dealers at about 7d. per ounce.

CAMEO PORTRAITS.—Can you inform me what preparation is put on the back of prints so that they may be pressed out in relief? Also, upon what sort of pad must the prints be placed to press upon, and any other particulars as to the method of making relief photos at home without having to have blocks made?—S. E.

By pressed out in relief we presume you mean what are known as "cameo portraits." Presses for reducing them may be had from any of the large dealers. The press is of the screw type, and is furnished with thick metal plates, with openings of the size desired. At the bottom of the press is a thick rubber pad. The print is put into position under opening, and the necessary pressure applied, to produce the relief, by the screw.

LANTERN WORK.—(1) What is the advantage of using regulators on gas cylinders when at work? (2) When used, can the gas supply be controlled by the jet taps? (3) For a good light how many feet of gas would be used in an hour?—W. MARTIN.

(1) The advantage of using regulators is that the gas is delivered under a constant pressure during the whole of the time of the show; obviously if there is no regulator used, the more the gas is used the less the pressure. (2) Most certainly. (3) It is impossible to answer this satisfactorily, because there are no data as to whether a blow through, or mixed jet, single or biunial, with a single lantern and blow through jet, the consumption of oxygen is about 5 cubic feet per hour; with a

mixed jet the consumption of oxygen is a little under this, and that of hydrogen a little more.

LOST SKETCH.—A lady having left a sketch of a gentleman's here for me to frame, it has got mislaid. I have searched everywhere but cannot find it. I have offered to copy and enlarge any photo she likes to bring of him. She not agreeing to this, I offered her 30s. in compensation. This she will not accept, but says she will take it into court. Could you advise me in any way?—E. LEACH.

There is, so far as we can see, absolutely nothing to be done but to allow the lady to proceed, and then for you to take a solicitor's opinion, who would probably advise you paying a small sum into court, when the onus of proof of the value of the sketch would rest with the plaintiff. Still we should advise you to have yet another search.

RIGHT OF REPRODUCTION.—A well-known firm of postcard publishers wrote me for my permission for them to reproduce certain photographs of a well-known theatrical. I gave them permission on condition that my name appears at foot of all prints, etc. The photo is not copyrighted, but was taken at my expense and invitation. I have just discovered that my name does not appear, but the publishers publish their name as the photographer. If I copyright these pictures, and they insist on omitting my name, can I claim any compensation?—PERCY.

If the photograph is now copyrighted, further issue of the reproduction can be interdicted, and damages can be claimed, but the owner of the copyright would have to prove that he had sustained damage, which is not always such an easy thing to do.

ANGLE.—Will you kindly answer the following questions?—What would angle be with (a) 6 inch focus on 6, and 8 inch plate; (b) 7 inch focus on 6 and 8 inch plate; (c) 9 inch focus on 6, 8, 11, and 14½ inch plate; (d) 14 inch focus on 8 and 11 inch plate; (e) 16 inch focus on 6, 8, 11, and 14½ inch plate?—STUDIO.

In the B.J. ALMANAC for 1905 there will be found, on pp. 1152 and 1153, a table and notes that will enable anyone to find this out for themselves. However, we do not mind doing it for our friend. (a) On 6 inch plate, the angle is 53 deg.; on 8 inch, 67 deg.; (b) on 6 inch, 46.5 deg.; on 8 inch, 59.5 deg.; (c) on 6 inch, 36.5 deg.; on 8 inch, 48 deg.; on 11 inch, 62 deg.; on 14½ inch, 77.5 deg.; (d) on 8 inch, 31 deg.; on 11 inch, 43 deg.; (e) on 8 inch, 28 deg.; on 11 inch, 38 deg.; on 14½ inch, 48.5 deg.

SHOP HOURS ACT.—Our town is about to adopt the Shop Hours Act, and I should be glad of your opinion (1) whether photographers are affected as regards studio work? If so (2) what about outdoor work? Also (3) can a trade stand out of the movement if they all agree to do so?—J. S.

In our issue for January 13, p. 22, there is a short note on the Shop Hours Act which puts the case very plainly. (1) Photographers are, we think, undoubtedly affected as regards studio. (2) Certainly not as regards outdoor work. No Act or local authority can prevent a man from taking negatives outdoors, whether for trade or other purposes, at any hour of the day and night. (3) If the majority of a trade oppose the application of the Act to their business, then "the local authority shall apply to the central authority to revoke the order in so far as it affects that class of shops."

STUDIO QUERY.—Will you please give me your help on the following questions?—What style of studio would be best to build in garden facing south (size of studio, 8 ft. by 20 ft.; size of garden is about 20 ft. by 45 ft.)? Also, please say what the height ought to be and how much wood at each end, and what colour paint and blinds to use for inside.—F. G.

You say in a garden "facing south," but you do not say the position the studio is to occupy or from what quarter it will be lighted—north, east, south, or west. The dimensions you give will be small for a studio if you require it for professional work, and, as you have space at command, we should advise you have it larger. Not knowing the aspect the studio will have, we cannot advise as to the blinds, etc. We should recommend you to get Bolas' work, "The Photographic Studio," a guide to its construction; it will give you a lot of useful information. It may be had through any of the dealers.

STUDIO QUERY.—I should esteem it a great favour if you would kindly advise me upon the construction of a photographic studio—height, length, breadth, amount of glass, side and top. The light would have to be either east or west. Which would be most suitable? I thought east light, with holland-colour blinds. The available space at my disposal would be suitable or convenient for a studio about 35 x 15 or 16 feet. If you give me an idea I will get plans drawn, and would like to submit them to you.—STUDIO.

The size given will be admirable for a studio. Either an east or a west light will do very well, but if the studio were of the ridge-roof form you could have both lights, which would be a convenience, as you could use the west light in the morning and the east in the afternoon, thus avoiding the sun troubling you. With this length and width six or seven feet at either end may be opaque. If you send a rough sketch of your idea we shall be pleased to advise you further. See answer to "F. G."

RETOUCHING.—Enclosed are four cabinet photographs, two retouched and two not retouched. Would you please give me your opinion of my retouching, and what salary I might ask for as a retoucher? I am eighteen years of age.—POT.

(1) All prints sent for our opinion upon retouching should be fully printed, toned, and fixed to show the detail. Untoned and unfixd prints cover a multitude of sins, both of omission and commission. Your retouching is too mottled in effect and broken up in the touch, and also very weak in the modelling. The whole of the working should be finer and the blending of the touches better attended to. Your best point lies in the fact that you are fairly good in preserving the likeness. A few lessons from a smart and experienced teacher would soon put you right, for there is room for very great improvement in your finish. (2) The salary you are worth is difficult to state; you are very young yet, and if you are relying solely upon your retouching, we should think about £1 per week; but, to be candid with you, the one print shows only second-rate work, and the other print not even that. But do not be depressed on this account; you have youth in your favour.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears on the text portion of the paper.

The British Journal of Photography.

The Oldest Photographic Journal in the World.

ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWOPENCE.

EX CATHEDRA.

The Constitution of Cyanine.

The abstract of a paper by Dr. Miethe, which we publish on another page, may frighten the reader who is not accustomed to the graphic formulæ of the chemist. But the abstract may give to those working with the dyes a hint of the possible variants which the chemist can produce. In another sense the paper is interesting. The constitution of cyanine has hitherto been taken as set forth in the text-books, and it will be something of an achievement if its photographic use and a photographic chemist's investigations of it should result in the revision of the accepted views. A former editor of this journal is reputed to have coined a phrase expressive of photography's humble part in research—"the Cinderella of the Sciences." Cinderella promises to transform herself into the fairy princess.

Rise in Price of Iodine.

A further increase in the price of iodine took place last week, when the Convention controlling the supply of crude iodine announced the figure of 10½d. per ounce. The present advance is one of a number which has steadily raised the cost of the raw material employed by manufacturers of iodine compounds from 3d. to the figure at which it now stands. The demand for iodine is chiefly in the drug trade, although the increased cost will be felt to a certain extent in photography. The position of the Iodine Convention appears to be an exceedingly strong one, and, according to the "Pharmaceutical Journal," there is a prospect of prices being pushed still higher. Even as the market stands now, it is estimated that the cost of production is nearer 2½d. than 10½d., a ratio which justifies

the reputation possessed by the Iodine Convention of being the best managed of such combinations.

The Chemical Society.

Photographic questions which may arise in the proceedings of the Chemical Society should be assured of support from the presidential chair, which is newly occupied by Professor Raphael Meldola, F.R.S., in succession to Dr. W. A. Tilden. Professor Meldola is one of the few scientific chemists who have taken a sympathetic attitude towards the chemical and theoretical problems of photographers. Nearly twenty years ago he delivered a course of lectures on the principles of photography to his students at Finsbury Technical College, and their republication in book form as "The Chemistry of Photography" has afforded the student an easy and agreeable introduction to the chemical facts and theories which underlie photographic practice. Although Professor Meldola has served on the Council of the R.P.S., and is reputed to number the camera among his means of recreation, his bent has been chiefly towards the scientific side, and he quotes the late Colonel Russell to the effect that photography would be a most interesting subject were it not for the pictures!

Postcards to and from Germany.

Our note of last week on the recent concession of the German Postal Department in permitting a written message on the address side of the card left in doubt the case of postcards passing between this country and Germany. We now learn, however, that the regulations of the Postal Union do not permit of such cards passing from one country to another, even when both allow of the circulation of the postcard in their own dominions. For this reason postcards having a written communication on the address side must be fully prepaid as a letter when posting to Germany.

The Carbon Process.

On another page, our friend "Historicus" describes Swan's original process of double printing, in which the temporary support as well as the exposed tissue was coated with a solution of indiarubber, and, when the solvent had evaporated, the two coated surfaces were pressed together in a rolling press. This seems a somewhat troublesome process, yet it was one that for some time was worked commercially by the Messrs. Mawson and Swan at Newcastle. We recently saw an excellent print, produced by them from a 15 by 12 negative by the late Mr. H. P. Robinson, "Waiting for the Boat," which was the presentation print of the old South London Photographic Society for 1866. This print, for delicacy of the half-tones and fineness of detail, is not surpassed by the most perfect carbon prints

of the present day. After Johnson's method (see "The Week in History," page 86 *ante*) and Sawyer's flexible support were introduced, rubbered paper went out of use in England.

* * *

Double Transfer with Rubber.

It may, however, interest our readers to learn that it is still used on the Continent by the firms that publish the fine reproductions of the paintings in the different national collections, and printed in carbon. They are by the double transfer method, and the temporary support is rubbered paper. It is, however, not worked as it was by Swan. The exposed tissue is not coated with the rubber; it is simply immersed in water; together with the rubbered paper, and the two squeezed together in just the same way as in the case of Sawyer's flexible support. When the print is finished, the transfer paper applied and become dry, the back of the support is passed over with a sponge charged with benzole, and the support stripped off. This, it is true, is a costly method of working, as the support, at the present price of rubber, costs as much, if not more, than the tissue itself, and it cannot be used a second time. But the publishers of the reproductions say that they cannot get the same excellence in their work by any other method of working the double transfer method of carbon printing.

* * *

Spontaneous Combustion of Celluloid.

Within the past month several cases have been reported in the German technical papers in which articles of celluloid spontaneously took fire. We hasten to qualify the sense in which we use the word spontaneous. Strictly speaking, there must always be a predisposing cause of combustion, and in writing now of spontaneous ignition we have in mind a chemical change of this kind occurring without actual access to a flame. The celluloid which has thus burst into flame has been chiefly in the form of ornamental articles of feminine toilet, such as the tortoiseshell hair-comb with which the suburban Daphne is able to crown her elaborate coiffure at a small expense. A correspondent of the "Chemiker Zeitung" records an accident which befel his wife as she knelt before a perfectly closed and not over-heated stove. Her celluloid comb caught fire, and the hair over an area of twenty square centimetres was severely scorched. Another husband describes a similar occurrence, but in this case the lady having washed her hair was seated near the stove waiting for it to dry. Still another instance is cited, in which the lady occupied a seat in church, at least 6 ft. from a stove, and in like manner fell a victim to the inflammable adornment of her hair.

* * *

Celluloid and Celluloid.

It is a pity that the facts as stated by the correspondents we have quoted are lacking in details. We should wish to have data as to temperatures and the composition of the celluloid before accepting without qualification statements which are opposed to the chemical properties of celluloid, and to the large experience of the photographic trade in handling it. Celluloid heated up to 280 deg. F. gradually softens. Between that temperature and about 400 deg. F., decomposition takes place and inflammable vapours are copiously given off. But nobody supposes for a moment that the temperature of any part of the comb even in the hair of the blonde German ladies could reach anything like these temperatures, and the only possible explanation which the facts, as crudely stated, appear capable of is that the articles were composed of celluloid of anomalous composition. It is not common to add mineral bodies to celluloid, but the presence of a

pigment is not at all improbable, and this latter, if of an oxidising character, might have supplied the conditions for ignition at a comparatively low temperature. The case is on record of a paper lamp-shade, coloured yellow with lead chromate, which spontaneously took fire, and some dangerous addition to the pure material would seem to have been made for the purpose of producing an ornamental article.

* * *

The Record of Pure Celluloid.

There can be no stronger refutation of the charge against celluloid of spontaneous inflammability than its career in the photographic trade. We cannot call to recollection nor find recorded anything of the kind, and that fact is the more important when it is considered that celluloid film, as part of photographic stock, is liable to be stored in all sorts of places without proper regard to temperature. A sharp distinction must be drawn between an article of unknown composition and a product which by the very necessity of the case has to be of the purest form obtainable. No evidence has been submitted to prove in the case of celluloid as used for photographic film that there is any liability to spontaneous ignition under possible conditions of temperature, which conditions, it may be added, are almost hundreds of degrees from the theoretical danger point.

* * *

Our Photographic Trade with Germany.

Some interesting figures are given in one of our German contemporaries as to our trade in photographic materials with Germany, from which we extract the following figures:—

	Imported to England in		Value.
	1903.	1904.	
	Kilogs.	Kilogs.	£
Optical Glass.....	33,300	16,200	20,124
Colour prints and Photos.....	2,559,100	2,700,900	1,100,621
Optical and Photographic Apparatus ..	13,400	19,800	46,737
Photographic Paper	572,500	627,500	340,089
Dry Plates	Nil.	Nil.	Nil.

	Imported from England in		Value.
	1903.	1904.	
	Kilogs.	Kilogs.	£
Optical Glass.....	Unknown.	Unknown.	—
Colour prints and Photos.....	98,500	142,600	84,580
Optical and Photographic Apparatus ..	Nil.	Nil.	—
Photographic Paper	33,800	27,700	11,399
Dry Plates	9,600	23,300	Unknown

We have included the figures for 1903, so that comparison may be made, but have not calculated out the value. Assuming that two dozen quarter-plates weigh one kilogramme, and this is approximately correct, and that the value is 2s., we can fill in the value in the last line of the lower table with the figure £4,660. Then Germany imports into England £1,406,522 worth of goods more than she takes from us. These figures do not take into consideration our Colonial Empire nor the trade in photographic chemicals, in which the difference would be very much greater, for probably the value of chemicals imported into Germany is infinitesimal. It would be as well to point out that "colour prints and photos." includes three-colour prints and other photomechanical processes, and possibly lithographs.

* * *

German Photographic Paper.

We learn that the shareholders of the Elberfeld Paper Factory Company, which is perhaps the most flourishing concern of its kind in Germany, have sanctioned the trebling of its original capital of £50,000. In 1903 the company paid an 18 per cent. dividend, while 1904 saw the shareholders in possession of one of 20 per cent., and they have naturally concluded that an increase of their capital would be a sound investment. It was stated at a recent meeting of shareholders that the money would be devoted

to purchasing the plant and materials requisite for the manufacture of photographic papers, from which large profits are expected. It is also significant that the factory at Steglitz (near Berlin), Germany's biggest photographic paper factory, also found itself unable to keep abreast of orders with its present plant, and had, therefore, decided to acquire fresh capital.

* * *

Geological Photographs. The British Association Committee for the collection of photographs of geological interest has issued its fifteenth annual report, and reports again a greater number of contributions than in any previous year. It is satisfactory to find that the interest shown by photographers in this application of their art is steadily growing, and that their services are generously appreciated by the geologists. Yorkshire is most largely represented, although Mr. Jerome Harrison sends 270 prints. The committee invite the honorary help of photographers in all parts of the kingdom, but particularly in the twenty-one counties on the "black" list, from which no work has yet been forthcoming. The report and a circular containing a number of notes on the technical side of geological photography is obtainable from the secretary, Professor W. W. Watts, Holmwood, Sutton Coldfield.

* * *

Dissolving Platinum. Some additions to the list of substances which attack metallic gold were mentioned in these columns a week or two ago. A paper on a somewhat similar subject now appears in the "Annales de Chemie et de Physique," in which the authors, Andre Brochet, and Joseph Petit, record the solvent action of potassium cyanide upon a large number of metals. A solution was used containing 250 grammes of potassium cyanide per litre. Among these experiments those on platinum are as interesting as any to photographers, since the authors find notable solution of the metal to take place in the cyanide solution. This, however, occurs only at a boiling temperature in the case of polished platinum foil, and no solution was observed to take place in the cold. Platinum black, however, might prove amenable to treatment with the cyanide, and we believe that the suggestion of cyanide as a reducer of platinum prints has been made.

* * *

The Hewitt Mercury Lamp. Modifications of the Cooper Hewitt lamp, as it has already been exhibited in this country, are stated to be in progress in America. According to a recent patent of Mr. Cooper Hewitt, the gas or vapour is effected by an intermittent flow of a current of practically the same value but of higher potential, the energy represented by the intervals between the impulses being intermittently withdrawn from action and reappearing in the form of an increased quantity in the rapid periodic currents. By the passage of current the voltage is lowered to a point where the usual resistance to starting re-forms, whereupon the checked current rebuilds or re-establishes itself, its electrical pressure rising until the breaking-down pressure is again attained, after which the same succession of actions is repeated. The result is stated to be an increased brilliancy on the part of the lamp due to this increased consumption of energy per unit of time, while the effect upon the eye becomes that of a light due to a continuous flow of current of greater quantity.

* * *

Nitro-Cellulose. A number of experiments which should assist in giving definiteness to formulæ in which nitro-celluloses are used for whatever purpose have recently been made by W. Will, and are described in

a recent report issued in Berlin. The author has sought to ascertain the influence of nitro-groups on the hygroscopic properties of cellulose, and in doing this he first takes as a standard of hygroscopicity the difference between the weights of the materials when dried in an ordinary oven at 40 deg. C. to a constant weight, and when exposed to an atmosphere fully charged with moisture at a temperature of 25 deg. C. for twenty-four hours. On examination of a large number of nitro-celluloses, varying in their contents of nitrogen from 8.20 to 13.21 per cent., he finds that the sum of the percentage of nitrogen of the hygroscopic moisture was constant in all cases with a value of about 14.6. This figure is unaffected by such operations as pulping, gelatinisation, treatment with dilute acids or alkalis or partial elimination of the nitrogen. The hygroscopic moisture depends solely on the percentage of nitrogen and shows no connection with the solubility of the nitro-cellulose in a mixture of ether and alcohol. The above generalisation, it must be understood, holds good only in reference to hygroscopic moisture as above defined. If the nitro-cellulose is dried over sulphuric acid or at different temperatures or for a longer time, the constant alters. Under the standard conditions, however, it would seem that Herr Will's figures should be of service in controlling the manufacture or supply of pyroxyline, since a fairly correct measure of the percentage of nitrogen can be made from the determination of hygroscopic moisture.

POINTS IN COPYRIGHT LAW.

In the "Answers" column this week two queries are replied to both of which are simple in themselves, yet each involves a point that may be of some interest, one in particular to those who make a feature of copying or enlarging for others. This query, in effect, is this: A postcard, marked "copyright" is brought to have an enlargement made from it. Are we infringing the copyright if we make it? The reply is certainly in the affirmative if there is a copyright in the picture, and that is not the property of the person who gives the order. Now, there is no necessity that a picture, the copyright of which has been registered, should be marked copyright, and, from the query, it may be fairly assumed that if the one in question had not been so marked it would have been dealt with as the customer desired—an enlargement made from it in due course. Had that been done, and the copyright in it had been registered, what would be the position of those who executed the order? This brings us to a point of considerable importance to those who copy and enlarge for the trade.

Suppose, for example, a picture is sent to them in the ordinary course of business to be reproduced in one form or another, and there is an existing copyright in it and they are not apprized of the fact, what is their position if action is taken for infringement? They are innocent agents in the matter, but, unfortunately for them, they will be liable to action as well as the one who commissioned them to do the work, and it will be no defence to plead that they were not aware that there was a copyright in the picture. We shall here quote from Mr. Macgillivray's excellent work, "The Law of Copyright" (page 179): "If a publisher procures a printer to strike off copies of an infringement, the printer is liable though he is entirely innocent. It was argued in *Baschet v. London Illustrated* that the printer was only liable if he printed for his own use, and if another caused or procured him to print, it was only the person causing or procuring who was liable. It was held that both the employer and employee were liable for the same offence." Here is another point in connection with

innocent agents that may be of interest to some. We again quote from the above work: "It will not avail a shop-keeper who sells pirated pictures as postcards and the like to plead that he was not aware that they were copyright." The above is sufficient to show the risks that those who, say, enlarge for the trade may at times run if they execute orders that are sent them if the works happen to be copyright ones. When a photographer sends one of his own original negatives it may fairly be assumed that he has the right to use it, but if the negative be a copy from another photograph, or picture, the case may be different. There may, possibly, be a copyright in that, and the sender, as well as those who execute the order, may both find themselves in trouble.

The second query of our correspondent also contains a point of some little interest. Does the printing of "copyright" upon a photograph ensure its being copyright? In all cases it does not, for we know that some few photographers mark their prints "copyright" although the copyright in them has not been registered by them, and that they were not legally entitled to the copyright if it had

been. We have seen portraits of sitters, taken in the ordinary course of business and paid for, marked "copyright." This is quite illegal. Copyright exists directly the picture is taken, but it is vested in the one who pays for it, and not in the photographer, unless it is duly assigned to him, and that must be done in writing. The printing of the word "copyright" with the name of the photographer on the mount implies that the copyright is his, and has been duly registered. The object, evidently, being to deter the sitters, or others acting for them, from reproducing copies of it, which they have a perfect right to do. It is illegal to attempt to prevent anyone from doing anything that they are legally entitled to do. The imprint copyright on an unregistered photograph, therefore, is obviously illegal. The marking of an article "patent" which has not been patented is illegal, and subjects the offender to substantial penalties—the maximum one being £20. Even if a patent has been applied for, and provisional protection granted, it is again illegal to mark the thing "patent," and very substantial penalties have been inflicted for so doing.

A NEW LIGHT FOR PHOTOGRAPHY.

IV.*

The Bastian Lamp.

On making inquiries some time ago as to the possibility of this lamp being adopted for photographic purposes, I was informed that it was only intended for general lighting, and that it was not contemplated to make it in a form suitable for photographic work. This was from the business agents for the lamp, but Mr. C. Orme Bastian, the inventor, on seeing my remarks in *THE BRITISH JOURNAL OF PHOTOGRAPHY* for February 3, wrote me pointing out that he could make his lamp as large and powerful as necessary for photographic work, and invited me to call at his works to see the various forms of the lamp he is now making. I am very pleased to have had the opportunity of investigating the Bastian lamp because it is really ingenious and has many commendable features. One naturally takes, moreover, a patriotic interest in an English invention, which in itself demonstrates that clever ideas do not all come from the other side of the "herring pond."

The Genesis of the Lamp.

Mr. Bastian has already made a reputation for himself through the introduction of a simple and cheap electric meter, and it was whilst experimenting with a mercury break switch in connection with his everyday work that he noticed the intensely luminous arc formed on breaking the mercury contact, this leading him to conceive the notion of utilising it for lighting purposes. Until that time he knew nothing about mercury-vapour lamps, and it was only upon inquiry that he found others had been on the same idea before him. However, he set to work on entirely original lines, and has evolved a lamp quite unlike any of the forms hitherto introduced or proposed.

Construction in Outline.

The lamp is arranged for suspending from the ceiling, and the top part is very much like the head of an arc lamp in appearance. With the cover on, it looks like a "bowler" hat and is not much larger. Underneath the rim, which is formed by a saucer-like enamelled reflector, the only mechanism visible is a couple of clips coming through from the head of the lamp to take the mercury tube. The latter is a zig-zag tube about $\frac{1}{4}$ in. thick and measuring over all about 5 in. Originally, I am informed, the tube is 10 in., and is crinkled down to

5 in. It is hung so that the undulations are in a horizontal plane, but at each end there are two short lengths of tube, very much like the end of a clinical thermometer, dropping down vertically. These are to contain the mercury when it has done its work of starting the arc. Platinum wires are sealed into the ends of the tube, and form the electrodes. The walls of the tube are tolerably thick, and the glass is one of the Jena varieties and withstands great heat. After the mercury is put in, the tube is connected to a vacuum pump and exhausted, whilst at the same time the mercury is boiled in the tube to drive off the occluded gases. No special pains are taken to get a high vacuum; indeed, Mr. Bastian says he rather prefers a little air in the tube as it lessens the impact of the mercury shaking about in the tube during transit. In some of the tubes he showed me minute air-bubbles were to be seen. The mercury is not specially purified, but no doubt the heating drives off most of any organic impurities. When the tube has been placed in its holder in the lamp head the action is that when the current is switched on it passes through a series coil, that is to say, a magnet coil traversed by the main current going to the lamp tube. The effect of this is to pull up the magnet core in the coil and tilt the lever on which are the two clips holding the lamp tube. The mercury which has been resting in the tube and forming a path for the current breaks away from one end and makes an arc, which is then maintained by the mercury vapour. The mercury is now resting in the reservoir at one end of the tube, and some is left in the reservoir at the other end. We thus have practically a mercury arc similar in a sense to the arc formed between two carbon points and maintained by carbon vapour. There is a difference, however, in the fact that the mercury, being in vacuo, is not consumed, as is the carbon. An intensely luminous greenish white light is the result.

Light for Electrical Expenditure.

On examination of the light spectroscopically we note that Mr. Bastian has been able to obtain an appreciable amount of the red, orange, and yellow rays into his light, and this may probably be the result of the high E.M.F. he prefers to maintain at the terminals. The lamp will work on any voltage from 100 to 300, and 200 to 240 is a preferable voltage. He cuts down the supply voltage by about 20 per cent. by means of resistance coils in the head of the lamp. These coils serve for

* The previous articles appeared on February 3, 10, and 17

regulating and steadying the lamp, which would otherwise make a "dead short" when the current was switched on. Two lamps can be placed in series on 500 volts. The current taken by the lamp is remarkably small, being only $\frac{1}{2}$ ampere. For this it gives an illuminating power of about 140 candles, measured by the ordinary standards, but its actinic power is much greater, photographically measured. I tested the light at a distance of 4 ft with Wynne's meter, and found that it took three minutes to darken to the quarter-tint. This may seem slow, but it must be remembered that the lamp tested was an ordinary one used for office lighting. By multiplying the tubes and making them longer it will be possible to proportionately increase the volume and strength of the light. A Hewitt tube, which is about 4 ft. long and $\frac{3}{8}$ in. diameter, darkens the actinometer paper to the same shade and at the same distance in thirty seconds, the current being $3\frac{1}{2}$ amperes in this case.

Life of the Tubes.

Mr. Bastian believes he will be able to arrange a number of tubes together in a suitable form for photographic work, switching on all at once. This will probably be better than having larger tubes. A great merit of the Bastian lamp is the comparative cheapness of the tubes, which can be renewed for 6s. each in their present form. Their life is guaranteed at 1,000 hours, but they may be good for 2,800 hours. If there is anything wrong with a tube it will show its faults within the first ten minutes. There is no danger of spoiling a tube by connecting up to the wrong poles, nor in case the lamp fails

to light up or goes out, as the mercury bridges the gap between the electrodes when the tube is in its "off" position. This is one of the patented features of the lamp, distinguishing it from all other types, as the invariable rule is to have the electrodes separated when the lamp is "off," so that the tube must be tilted to run the mercury down and make a contact.

Amalgams Instead of Pure Mercury in the Lamp.

Mr. Bastian showed me some interesting experimental lamps he has made with amalgams of various metals. One lamp of cadmium-mercury amalgam is very promising, giving a softer and somewhat more agreeable light than the plain mercury. A sodium-mercury amalgam was even better, giving a light more approaching that of the carbon filament. One ingenious way of modifying the greenness of the light was to put in parallel with the mercury tube another tube of larger diameter containing a special carbon filament just brought up to an orange glow. When a matt glass globe was placed over the lamp the effect was very pleasing.

Mr. Bastian has experimented with amalgams of almost all the metals, and a most interesting lamp is one containing rubidium, which was described as giving a "crushed-strawberry" colour. The colour appears, however, only intermittently and seems to be most pronounced when the voltage is raised. When at its best the light shows a brilliant red band in the spectrum.

In conclusion, I may say that the Bastian lamp in a form suitable for photographic work will not be on the market just yet, but when it is it will, I venture to predict, be exceedingly useful and highly popular.

WILLIAM GAMBLE.

THE CHEMICAL INWARDNESS OF THE CYANINE DYES.

THE following brief and popular abstract of Dr. Miethe's paper in the "Berichte" (No. 8, 1904, p. 2008) will explain not only the new view of the constitution of these dyes, but also the method by which Drs. Miethe and König prepare the recent numerous cyanine sensitizers of gelatino-bromide emulsion. Each dye, it will be noticed, has a chinoline and a chinaldine component, and by selecting these constituents, first modified by introduction of halogen, amidogen, and other groups, the later variants of ethyl red have been produced.

Even the scientific dilettante may be excused if he recoils in horror from a page of organo-chemical research in compounds of high complexity, and few classes of carbon compounds can "go one better" in point of intricate linking of their constituent atoms than the derivatives of quinoline, otherwise chinoline, which form the basis of the cyanine dyes. To begin with chinoline itself, its formula, C₈H₇N, tells us next to nothing. We must know its "constitution," and that is represented thus:—

Fig. 1.—Quinoline or chinoline.

N. Now, chinoline is only the starting point on the way to cyanine and isocyanine. It combines with ethyl iodide, forming chinoline ethyl iodide:—

Fig. 2.—Chinoline ethyl iodide.

and this again undergoes conversion into

Fig. 3.

being derived from two molecules of benzene (which have joined at two points), in one of which the C H has been replaced by

The remaining member of these weird dramatis personæ in the chemical drama is chinaldine, or quinaldine. It is simply

chinoline with one of the hydrogen atoms taken away and replaced by the radical methyl. Its picture formula is:—

Fig. 4.—Chinaldine or quinaldine.

and, like chinoline, it forms the ethyl iodide and the O H compound which we have numbered rather than named. Now we can come to the real point raised by Dr. Miethe, which is not so hopelessly above the elementary chemical student as might be thought. How is ethyl red made? By the action of chinaldine ethyl iodide on our friend No. 3 of the chinoline family. The two molecules unite with the splitting off of water. In the chemical under-world many transactions and amalgamations are signalled by the emission of water, in fanciful contrast to the human sphere, where absorption of liquid is observed at similar functions. However, the ethyl red which is thus formed has been held to have the constitution:—

Fig. 5.—Ethyl red: Constitution as hitherto supposed.

We have taken the liberty of turning the chinaldine ethyl iodide molecule upside down, in order that its behaviour may be more clearly discerned; not that it is in the slightest affected thereby.

Here is the constitution of ethyl red, according to the orthodox view. Not according to Dr. Miethe's. He affirms it to be incorrect, and he extends his strictures to the cyanines as a class. And the reason? Well, ethyl red is a substance which combines with two atoms of iodine; and in formula No. 5 the only place for the two iodine atoms is in union with one or other of the nitrogen atoms. In either case the compound which results is a per-iodide. But ethyl red, treated

with iodine, does not behave like a periodide, and it would seem that some other constitution of the complex molecule must be found. Dr. Miethe argues, from certain experiments, that the chinoline ethyl iodide does not form our friend No. 3, but a somewhat similar body, γ chinolon.

Fig. 6.— γ -chinolon.

In doing this, two atoms of hydrogen are given off, and they reduce the chinaldine ethyl iodide to the substance:—

Fig. 7.—Reduction product of chinaldine ethyl iodide.

which latter combining with the γ -chinolon forms ethyl red, thus:—

Fig. 8.—Ethyl red, according to Miethe.

This the reader will see is a different kind of linking from the previous one. Now it can take up two atoms of iodine without masquerading as a per-iodide, which it is not. For the iodine can enter the molecule at two separate points, attaching itself to the carbon atoms. The same argument applies to other cyanine dyes, and the theory of their formation is mollified if Dr. Miethe's theory prove to be correct.

THE WEEK IN HISTORY.

The Genesis of Carbon Printing.

If Sir J. W. Swan derives pleasure from the celebration of anniversaries or from dwelling in reminiscence on his share in photography, then he has my condolences on the date on which he applied for his "carbon" patent in the year 1864. His application was entered on February 29, so that carbon printing has only celebrated one quarter of the birthdays which might have been its, if its inventor had been a day earlier or later. Though the patent has the general title, "Improvements in Photography," it is concerned with a very particular department of the art. It claims protection for a method of developing prints in bichromated gelatine from the back. Swan was not the first to recognise the fact that if you want to develop a print in "chrome-gelatine," you must attack it at its soluble surface. In other words you must stick down the face of the exposed film to some support and develop the back. Further than this, Swan was not the first to devise some sort of a process by which

this could be done. Burnet, Blair, and Fargier had dealt with the problem, but none of them had arrived at a solution which could be applied commercially. This was accomplished by Sir J. W. Swan, as was also the re-transfer of a print to a final support, and the manufacture of a pigmented tissue or paper which could be supplied ready for use, or needing only to be rendered sensitive.

The First Transfer Processes.

As described in the patent specification, the transfer process was as follows:—The exposed print was floated on a solution of indiarubber in benzole of strength about six grains of rubber per ounce, and containing in some cases also a little gum-dammar or gutta-percha. A piece of paper was treated in like manner, both allowed to dry, and then pressed together, with the exposed surface of the print in contact with one side of the rubber-coated paper. This was done in practice by passing the two, in contact, through a rolling press. Rubber was the cement

used if the prints were to be transferred a second time in order to obtain a print non-reversed as regards right and left, but if the reversed print were left permanently on the first transfer paper, a cement of albumen or starch was recommended. "I then," continues the patentee, "submit the mounted tissue to the action of water sufficiently heated to cause the solution and removal of those portions of the coloured gelatinous matter of the tissue which have not been rendered insoluble by the action of light during exposure in the printing frame or camera. Where paper has been used as a part of the original tissue, this paper soon becomes detached by the action of the warm water, which then has free access to the under-stratum or back of the coloured gelatinous coating . . . I allow the water to act upon the prints during several hours, so as to dissolve out the decomposed bichromate as far as possible. I then remove them from the water and allow them to dry."

The Wet Collodion Process.

The first decade of photography was an anticipation of its position sixty years later. It was an epoch of negative-making on flexible materials. True the metal plate of the Daguerrotype was largely in evidence, but, for the rest, practice and progress concerned paper negatives. Nevertheless there was an under-current of reaction from paper processes, and efforts were made to prepare glass plates for the reception of the sensitive silver salts. Albumen was the material chiefly in favour for this purpose, and numerous processes in which it is used will be found scattered through the literature of this period. It was not, however, until 1851, that photography on glass plates entered the realm of practice. In that year, in the March number of "The Chemist," appears a paper "On the Use of Collodion in Photography," by Frederick Scott Archer. It describes in detail the method employed by him, and so I quote from it, though I do not imagine that modern workers will elect to prepare their silver iodide as Scott Archer did.

From Paper to Collodion.

I find from numerous trials (wrote Archer) that collodion, when well prepared, is admirably suited for photographic purposes as a substitute for paper. It presents a perfectly transparent and even surface when poured on to glass, being in some measure tough and elastic, and will, when damp, bear handling in several stages of the process. I will now give a

short outline of my method of using it. The first step in the process is to prepare the solution of collodion. There are several ways of doing this, but I will briefly allude to two.

Pour a quantity (say, one ounce) of collodion into a bottle containing dry iodide of silver. Shake them well together, and then allow the excess of iodide to settle. The collodion will, in this way, take up a certain quantity of the silver salt and become opaque; it should then be transferred to another bottle containing iodide of potassium, to be again well shaken up until the iodide of silver is entirely dissolved, and the solution becomes perfectly transparent.

Or this:—To a solution of iodide of potassium in spirits of wine, add a small quantity of iodide of silver to saturate the iodide of potassium; if, however, the latter salt be in excess, add a small quantity of this solution to the collodion, between five and ten grains (by measure) to one ounce of collodion will be sufficient, and if any of the iodide of silver should precipitate, a small quantity of iodide of potassium must be added to dissolve it.

Collodionising and Sensitising.

The next step is to spread this solution evenly on a plate of glass. This can be done by pouring a sufficient quantity on the glass to run in a body freely. When it has entirely covered the glass plate, let the super-abundance be drained off at one corner into the bottle again; this operation cannot be done too quickly, for the ether rapidly evaporating would prevent the collodion running evenly over the surface of the plate from becoming too thick.

The plate is now plunged into a bath of nitrate of silver, allowed to remain there for a few seconds, and then washed in water. (This washing is intended to remove all the ether from the surface of the collodion, which, if allowed to remain would cause an unevenness in the sensitiveness of the surface, producing streaks or spots.) Immediately after washing, it may be exposed to the action of light for the time necessary to obtain a picture. The picture can be developed either by gallic or pyrogallie acid . . . After the picture is developed, the film of collodion should be loosened from the edges of the glass plate with a flat glass rod. By doing this it will easily separate from the plate, and can be allowed to float freely in the water bath previous to being placed in the bath of hyposulphite of soda and then again thoroughly washed. HISTORICS.

SOME PROBLEMS IN SHUTTER DESIGN.

[A Paper read before the Royal Photographic Society.]

AN examination of the Patent Office records for the last twenty years shows that hardly any part of the apparatus used in photography has been more the subject of invention than has the exposure shutter. And yet the modern shutter, the product of all this study and invention, is admittedly very far from perfect. A writer in "Photography" has recently characterised shutters in general by saying:—

"You set them for 'time,' and they open for all eternity, or you set them for 'instantaneous' and make the speed a quarter of a second, and they don't open at all. If the shutter should by any chance succeed in both opening and shutting, the only speeds it will give correctly are those that are not marked on the indicator."

This is of course a caricature. It conveys truth by exaggeration.

There are, indeed, some excellent shutters on the market; and in particular I would mention the Goerz "Sector" shutter, the Bausch and Lomb "Volute," and a number of focal plane shutters.

But the truth regarding shutters is well expressed by Mr. Chap-

man Jones in his book on the "Science and Practice of Photography," where he says of focal plane shutters:—

"If an exposure of each part of the plate of from one-hundredth to the one-thousandth of a second is required, probably this type of shutter is the best; indeed, it is the only commercial shutter that will give the shortest exposure mentioned. But it should never be used when a shutter at the lens is possible, because it distorts the image of the moving object."

And of between-lens shutters he says:—

"Such shutters, if good, are very costly and very excellent; if cheap, they are not reliable. It is not usual in a cheap shutter of this kind, marked, to give exposures extending down to one-hundredth of a second, to find that the two or three most rapid exposures are practically the same, and none of them shorter than about the thirtieth of a second."

The Ideal Shutter.

For some time I have been studying to produce a commercial—that is, inexpensive—between-lens, diaphragmatic, automatic shutter,

which, however, is not yet quite ready for the market. It is only the problems of tool making, involved in its production in quantities on an interchangeable and economical basis, which delay its final production.

My main object, however, while describing this shutter, is rather to lay before you certain fundamental considerations regarding shutters and shutter action which so far as I know have not yet been publicly discussed.

The ideal photographic shutter, among other things, occupies no time in opening, and none in closing, and remains fully open during the whole interval of exposure. This effect is attained by the focal plane shutter, which acts by uncovering successive portions of the plate which receive at once the full volume of light passed by the lens.

With such a shutter, the duration of the exposure is a direct measure of the exposure value, and the exposure may be graphically represented by the rectangular diagram *a*, Fig. 1, and stated as having an efficiency of 100 per cent.

Between-Lens Shutters and Efficiency.

From between-lens shutters, which act by uncovering successive portions of the lens, we cannot, however, get an efficiency of 100 per cent., because during the opening and closing of the shutter the volume of light received by the plate respectively increases and diminishes, and is at its maximum only while the shutter remains fully open. When this interval is long in comparison with the time occupied in opening and closing, the efficiency of a between-lens shutter may be high; and diagram *b* represents the action, during a total time of one-twelfth of a second, of a shutter which occupies only one-hundredth of a second in opening and closing. With such a shutter the total duration of exposure is, within 3 per cent., and therefore for all practical purposes, a measure of exposure value.

Diagrams *c* and *d* show the corresponding efficiencies of exposures lasting for one-twenty-fifth and one-fiftieth of a second respectively,

85 SHUTTER EFFICIENCY DIAGRAMS.

Fig. 1.

Diagram *e* shows the action of the shutter when it commences to close immediately it becomes fully open. If this shutter moved at a fixed velocity in opening and closing, and if the light passed by the lens increased directly in proportion to the shutter movement, then the triangle *f* would represent its action, and its efficiency would be only 50 per cent.

What is the "Speed" of a Shutter?

But the shutter blades do not move with a fixed but with an accelerating velocity; and a diaphragmatic shutter admits light, not in proportion to its movement but to the square of its movement. Thus we have an acceleration of motion coupled with an acceleration of

light effect which together produce a diagram of the general form of *e*. In such a diagram, the length of the base, the duration of exposure, is very far from representing the exposure value. It does not even adequately express the duration of effective exposure, for we may, as the diagram shows, cut off the left-hand corner and thus reduce the duration of exposure by one-fourth, without taking away more than about one-hundredth part of the area of the diagram which represents the exposure value. This part of the duration of exposure being obviously, then, a negligible quantity, it is clear that the common practice of measuring only the total duration of exposures when testing the value of shutter "speeds" is of even less value than is commonly supposed.

The every-day practical photographer who aims to get accurately exposed negatives, and who relies for this purpose upon the "speeds" marked on his shutter, needs that those "speeds" shall be, not the total durations of exposure, but the net effective exposures. On the other hand, the comparatively rare case of the photographer who calculates the limit of exposure duration necessary to avoid blurring of a moving object is the only one in which the measurement of exposure duration is of vital importance. I therefore think it most unreasonable that the accuracy of speed marking upon shutters should be criticised only from the standpoint of exposure duration, as is done notoriously at the present time. I would make the effective exposures the "speeds" marked upon a shutter, these being what are required for ninety-nine purposes out of every hundred; and I would give, if necessary, for the odd hundredth case a statement of the actual exposure durations.

I have used the term "speed" of a shutter so far in the ordinary sense, which, however, is wrong and should be avoided. Speed indicates velocity; but with such shutters as we are considering the velocity of motion is constant for all exposures. What varies is only the interval of time during which the shutter remains open. Time, then, and not speed is the word which carries the meaning we wish to convey.

Fig. 2.

"Hand" and "Automatic" Exposures.

The improper use of the word "speed" has arisen from its legitimate use at the time when, in ignorance of the principles already discussed, we varied the times of exposure by varying the speed of the shutter's motion. From the same early days we inherit the terms "time" and "instantaneous," which are now misapplied to dis-

tinguish between exposures determined by hand and those which are governed by pneumatic or other action automatically. Hand and automatic exposures are more suitable terms.

A Modified Iris Diaphragm.

The same process of development has left with us, in the ordinary diaphragmatic shutter, some of the defects of the original

Fig. 5.

Iris diaphragm upon which it was based. Messrs. Dallmeyer and Beauchamp, in 1838, were, I believe, the first to apply the idea of

the Iris diaphragm in the construction of shutters, and Messrs. Bausch and Lomb, Goerz, and others have since improved upon it.

But not much has been done in the direction, in which for a shutter most improvement is needed, of reducing the weight of the moving mass.

High velocity of the diaphragm in opening and closing is necessary to secure short exposures or high efficiencies; and this makes the reduction of mass a vital matter, especially with an automatic shutter where the store of energy is limited; for the energy required is proportionate to the mass moved and to the square of its mean velocity.

The original Iris diaphragm, and the shutters which have been evolved from it, consisted of a number of pivoted segmental leaves each forming one side of the polygonal opening, and all moved simultaneously by the rotation of an annular radially-slotted plate. Fig. 2 shows, however, that it is possible to make such segmental leaf contribute two sides to the polygonal opening, thus reducing the number of the leaves by half, and Fig. 3 is a shutter diaphragm which will open to .85 of diameter, formed by four such leaves having a total weight of only 13 grains, connected not by the usual heavy slotted plate, but by four crossed links weighing only 17 grains. The total effective mass is in this way reduced to a fraction of what is usual, the forces are balanced, and high velocity without shock is made possible. A simple reciprocating motion imparted to one of the link pivots will actuate this diaphragm.

WILLIAM TAYLOR.

[The remaining portion of Mr. Taylor's paper will appear next week.—Eds. B. J.]

TIME DEVELOPMENT.

RECENTLY, before the Society of Arts, a paper was read by Mr. R. Child Bayley entitled "Time Development in Photography and Mechanical Methods of Carrying It Out." The chair was occupied by Mr. George Davison. The lecturer introduced the subject by comparing the conditions of development of wet and dry plates. Wet plate development, essentially a process of silver intensification, had to be controlled by inspection, and it was implied that the methods of developing gelatine plates by examination were perpetuated by the present-day photographer out of his experience in wet plate, or had been handed down to him by the older workers. In the early use of bromide as a corrective of over-exposure no attention was paid to erroneous tone values, and the lecturer dated the inclusion of correct gradation in the consideration of such methods from Mr. W. E. Debenham's suggestion to take as the basis of the Warnerke plate speed, not the faintest perceptible image recorded by the instrument, but only those parts in which there was a printable image. The basis of time development, the lecturer proceeded, was supplied by the researches of Hurter and Driffield on sensitometry, and the effects of developers on gradation. The alterations in the developer as they are generally made by photographers did not affect the density ratios of the negative. It was possible to alter the curve of densities enormously, but not by alterations in the developer of practical importance. "Given a developer which does not fog the plate, which is free from solvents of the silver salt, such as ammonia, the only way in which the straight part of the curve can be modified is in the angle, which, when produced, it makes with the base line." Arrived at this point in the review of development methods with which the lecturer prefaced the treatment of his subject, we may quote the paper in extenso from the "Journal of the Society of Arts":—"Although, generally speaking, this remark

holds good of alterations of the active developing agent, as well as of alterations in the strength and composition of a solution in which the active agent is always the same, there are certain developers, the use of which shifts the point of intersection very considerably. The result is that with these developers the plate is faster or slower than it is with others, a fact pointed out by Hurter and Driffield in their very first paper. Such alterations, however, are not used as methods of control, although, where the shortest possible exposures are demanded, photographers may use such a developer as will make their plates give a faster reading than the re-agent which they generally employ.

Development and Incorrect Exposure.

"The variation which we get by alterations in the composition of the developer, such as used to be recommended for the cure of incorrect exposure, can be effected by alteration in the time of development, in the temperature of the developer, and in the composition of the developer, or in two, or in all three. As it is always desirable, where control is to be exercised, that the control should be direct and simple, it follows that, since all the useful control we can effect can be got with variation in the time only, there is no need to vary the other factors, and one uniform developer, applied at a known temperature, will do all that we can require of it, provided the exposures have been correct.

"Here, then, we have the basis of time development. The development of the plate is effected by a standard developer at a standard temperature, any control required being obtained by altering the time of development and that only.

The Practical Aim in Negative Making.

"Theoretically, we can alter the time of development in each case to obtain negatives to suit various printing processes, or to make

different classes of subjects suitable to the same printing process, and to some extent this is done. Thus we hear of negatives being made 'strong' because they are wanted for carbon work, or 'kept thin' for enlarging. At the same time, it often happens that the result aimed at in this way is not attained, and many a photographer whose work is of a varied character, uses two or three different printing processes, so that he may be able to print a negative by the method best suited to it, whether that method was what he aimed at in development or not. The utilisation of the entire range of a printing paper is comparatively unimportant, and a negative with a development factor of 1.2, expressed in the Hurter and Driffield manner, if correctly exposed, will give a result by most printing processes (except perhaps by straightforward enlarging on bromide paper), to which the most captious would not take exception.

It is interesting to note, in this connection, that using the developing powders supplied by Kodak, Limited, with Kodak film in the Kodak machine, to which I shall refer shortly, exactly as specified, gives us a development factor of 1.1 to 1.3.

A Working Average.

"This question of the development factor is an important one, as it is that on which there is the greatest degree of misconception. It has been urged against the proposal to develop for a fixed time that a development factor that suits a portrait does not suit a landscape or an interior. Strictly speaking, this is perfectly true. In the same way, to get the best possible results, quantitative experiments have shown us that we require a higher development factor for negatives that are to be printed in carbon than for those that are to be printed in platinum, for platinum than for ordinary silver paper, and so on. But actually, and in every-day practice, the professional portrait photographer is the only worker who aims definitely at a result suitable for one particular printing process and that only. The average photographer, amateur and professional, aims rather at an average result, he wants a negative which will suit him for any process he may fancy. Nay, more, he expects the same negative to give him a good contact print, and a good enlargement. Yet on the same printing paper, the former requires a very much higher factor than the latter, two-thirds as much again in point of fact.

"To do this he must aim at an average result, and to tell the truth, a plate that has been correctly exposed and developed for such an average result is so much better than nine-tenths of the haphazard results of incorrect exposure and 'controlled' development, that those whose photography has merely for its aim excellent prints, and is not carried out with a nobler polemical purpose, are more than satisfied with it.

"Such an average result, it will be found, is to be obtained by timing the development so that the factor is approximately 1.1, which it will be seen is not very far from the figures given by the Kodak method.

"If we have a correctly-exposed plate, and we develop it invariably in a standard developer at a standard temperature for a length of time to suit that particular plate, we shall find that it will give us a negative, not in every case as theoretically perfect as it could be made with more elaborate precautions, but a great deal more perfect than it could be made by any empirical procedure guided by mere ocular examination; and that not once, but every time, with a minimum of trouble and a complete immunity from light fog.

Under Exposure.

"So far, I have been speaking only of correctly-exposed plates. Let us now consider the question of incorrect exposures. The development applied to a correct exposure should be that best calculated to suit an under-exposed plate. For manifestly, if with much shorter exposure we could get the theoretically perfect negative by any modification of the developer, that would be the course to adopt in

practice every time. No one wilfully throws away rapidity in an emulsion. And, as a matter of fact, it is so. An under-exposed plate developed by time as if it were correctly exposed, gives us the best possible result we can hope to obtain. Clear, but lacking in vigour, if the under-exposure is not too great, the plate can be intensified up till it attains sufficient contrast to print. It will never be a 'perfect negative,' either theoretically or practically; and I am not aware that any method of making it so has ever been devised.

Over Exposure.

"The question of over-exposure is one which requires more consideration, because there are many photographers who believe that methods they employ enable them to determine during development whether a plate has been over-exposed or not, and if so, to remedy it so that in the final result the change brought about by the excessive exposure has been entirely counteracted during development, and the plate shall in no way differ from one correctly exposed and normally developed. The belief takes its origin in the old practice to which I have already referred, of judging a negative, not by the truthfulness of the whole of the gradations upon it, but by the visual appearance of its highest and lowest tones, by its clearness and contrast, in short. The most obvious difference between an over-exposed and a correctly exposed plate, when both had been developed until the highest lights were equally dense, was that the former had much more deposit in the shadows, and, in consequence, much less contrast all through. A method of development which gave the plate contrast and prevented much of the blocking-up in the shadows, was supposed to cure the over-exposure.

A Sense of Incorrect Tone Values.

"The moment methods of measurement more accurate than ocular examination were applied to such negatives, it was seen that, so far from the over-exposure having been cured, its effects were as marked in such negatives as if they had been developed in the ordinary way. The density of the highest light and of the deepest shadow had been made to correspond, perhaps, with those on the plate that was correctly exposed, but the intermediate tones were as untruthfully rendered in the abnormally as in the normally developed plate. It is a curious fact that, while this method of 'curing' over-exposure has satisfied that large body of photographers whose tastes are not sufficiently scientific to lead them to examine the subject for themselves, and whose artistic sense is not sufficiently keen to show them the essential falseness of the results so attained, I have known several workers, without the slightest claim to any knowledge of the principles of development, whose sense of tone value was sufficiently acute for them to detect at once that there was something, wrong in these cases of fancied cure. They could not put their fingers on the cause, as we can now, but the symptoms to their trained observation were patent.

The Remedy for Over-exposure.

"All the investigations of the last fourteen years go to show that over-exposure is not in any sense curable by methods at present available. Prevention, says the proverb, is better than cure; and some of those who think it their duty to defend practices long since shown to be unsound, only do so by revealing their incapacity to grasp and employ preventive measures. If over-exposure cannot be remedied, the question still remains, what is the best way of dealing with it?

"To answer that question, let me put another. If modification of the developer will not bring about the change we require, why should we modify it? The simplest and most efficient plan to secure results from over-exposed negatives is to develop them for the same length of time and then either to print them as they are, which presents no difficulty with development papers, or to reduce them with such a solution as the ferricyanide and hypo reducer until they

are sufficiently thin for the purpose required. But let me add once more that neither this nor any other device 'cures' the over-exposure. It only makes the best of a bad job.

The Importance of Correct Exposure.

"It will be seen, therefore, that the result of the investigations of exposure and development which so far have been carried out, points to two conclusions:—

- "1. The supreme importance of correct exposure.
- "2. The powerlessness of modification of the developer to remedy errors of exposure.

"I hope that I have made clear that from these two conclusions we can draw a third, namely, that if all our negatives receive identical development, identical, that is, as regards composition of developer, temperature of developer, and time of development—provided that treatment is the best for a properly exposed plate—it is at least as good for all as any series of modification can be.

"So far, however, we have only reached the conclusion that it is as good as other methods. We will now see whether such a method brings with it any other advantages. Manifestly, if we are going to treat all our exposures alike, the need for some method by which we can watch the development of the plate vanishes. We neither have to determine from its appearance whether to modify the developer or not, nor when development is complete.

"This brings two advantages in its train.

"The risk of light fog, or rather the degree of light fog is reduced, because every plate developed in the dark-room, as we know it, is fogged more or less; generally, I am afraid, more rather than less. No light worthy of the name is 'safe' for prolonged development; and although I am aware that such an objection may seem hyper-critical, and my audience may know that in their own practice those of them who develop in the dark-room get negatives to all intents and purposes free from fog, the enormous majority of the negatives which I see, and I see many hundreds in the course of a year, are fogged, and badly fogged, either from the dark-room illumination, or from an unsuitably compounded developer, or from both.

When to Stop Development.

"Quite apart from the risk of fog, the determination of the point at which to take the plate out of the developer is a difficulty even with the most experienced photographer, if his only means of ascertaining it is by looking through the negative at the light. The apparent contrast obtained is not necessarily the actual contrast, since it is affected very largely indeed by the thickness of the coating of emulsion on the plate, and to a small extent by the brightness of the light by which it is examined. This latter may be made constant, but the former cannot; and although modern machine-coated plates are remarkably uniform as far as any one batch is concerned, I have found considerable differences in the thickness of the coating on plates of the same brand but made presumably some days or weeks apart. When the conclusion of development is settled by the clock these sources of error disappear entirely, and hundreds or thousands of plates can be developed with a degree of uniformity which is to be attained in no other way.

Arguments for Time-Development.

"It is for these reasons that a good many years ago now I became a convert to the method of working known as time development. Its advantages may be summarised thus:—

- "1. It gives us perfectly uniform negatives when exposure has been correct, whether we develop daily, or only have a few to deal with every now and again.
- "2. It brings everything out that can be got out of an under-exposed plate, and removes the temptation to over-develop in the hope that more details may be obtained.
- "3. It gives us as good a result as can be got with over-exposed

plates, and prevents any risk of insufficient development which may be caused by the difficulty of judging how far development has gone when the plate is very opaque.

"4. It reduces light fog to a minimum, and in the case of roll films does away with it entirely.

"5. It overcomes entirely the difficulty of determining when development is complete.

"6. It can accommodate itself to the nature of the subject or to the printing process to be used, or may be settled once for all to give a good 'all-round' negative."

[The remainder of the paper, in which are considered the mechanical methods of time development, will appear next week.—Eds., B.J.]

Photo-Mechanical Notes.

Process Work in India.

In the lecture given at the Bolt Court School on 9th inst., a report of which appeared last week, Major-General Waterhouse referred to the climatic changes which trouble the worker in photographic processes. "In Calcutta," he said, "there were practically three seasons, with two indefinite intervals between them, viz., the cold season, from about the middle of November or beginning of December to the middle of February, the hot season, from March 21 to the middle of June, and the rainy, from the middle of June to the end of September. Therefore about the middle of February solutions had to be changed to hot weather formulæ, and in the middle of November to cold weather. In the same way after the middle of February the softer kinds of gelatine dry plates could not be used without ice or special treatment when developing.

"In regard to the effect of the Indian climate on health the advantage of Calcutta over Bombay and Madras was the cold weather from November to February, which gave just enough change to set one up. There were those, of course, who preferred the climate of Bombay and Madras to Calcutta. Another advantage of Calcutta is that the nights are nearly always sensibly cooler than the days, and this is a great point, especially as compared with the towns of Upper India, where there is no remission of heat night and day, and no feeling of relief. There are many openings now for young men in India, and none need be deterred by climate if in good health and steady livers."

Half Tones from Clay Models.

Now that there is such a demand for half-tones from clay models the good operator should look into the matter and find out the best way to work them in his shop. The usual method is to have an ordinary photograph made and work from that. This is all right to a certain point; but you can't always get a good photograph made. The average gallery man knows little about mechanical work and it takes time to explain it to him. But the best, and also the quickest way is to make your half-tone negatives direct from the clay. The matter only requires a little study and even if you do have to make three or four or even five trials it is not so expensive and is much quicker than sending the job out to the nearest gallery. And then you have in your two arc-lamps a sharper and more controllable method of illumination than any gallery. By leaving one lamp in its usual place and moving the other away you can get any depth of shadow desired. As a usual thing there is so much reduction from the original that the depth of the model is of no importance. Should this be apparent it is an easy matter to work with a set of smaller stops, less separation, and, if necessary, put out one of the lamps during part of the exposure in order to get contrast.

Making Stops of Cardboard.

Writing to "Camera Craft," an operator complains of difficulty in a run of work which included photographs with a great deal of light, flat sky. The skies "would not come smooth and even." Everything about his shop appeared all right. Negatives bright, clean, and sharp, and the print on the copper "looked" all right. But when it was etched it was all wrong. Apparently the difficulty was in the etching, but eventually it turned out to be in the negative. One of his stops was so carelessly cut that its deficiency from the rectangle was apparent to the eye. Comparison with the other stops showed a perfect tangle of lines. When this was known the defect was apparent in all the negatives. At certain intervals the crossing of the lines was irregular and the corners quite rounded. Of course the printing and etching only intensified this defect. On jobs with broken tints such a defect would not be noticed, but it goes to show just how important a perfect stop is. Make your stops with a compass and T square. A negative can be made with any kind of a stop provided it is accurate.

A Commercial Adjustable Diaphragm.

The difficulty of the operator quoted in the above paragraph would not have occurred had a diaphragm of the form recently put on the market by Messrs. Penrose and Co. been at hand. This stop, which is the design of Mr. W. J. Smith, a student in the Bolt Court School and a contributor to these "Photo-Mechanical Notes," possesses two adjustments. As seen in the figure, there are two sliding leaves,

which enable a square opening of any size to be obtained; extra leaves being provided for an elliptical stop, or a square one with two corners extended. The second adjustment provides for the angling of the opening to correspond with the screen ruling, according to the requirements of three-colour work. The one instrument thus accomplishes all that need be done with a diaphragm without disturbing any of the adjustments of the camera or lens. The diaphragm, which is made by Messrs. Taylor, Taylor, and Hobson, is stocked by Messrs. Penrose for the various sizes of "Cooke" process lenses. The standard system of marking corresponds with the graduation of the diaphragms already used by Messrs. Penrose, but the stop can be marked in inches or millimetres to suit individual requirements. The diaphragm should certainly prove of great advantage to process-workers.

WALLINGTON Camera Club.—The first annual exhibition of this club will be held at the Christ Church Lecture Hall, Wallington, on April 4, 5, and 6. Four open classes are announced, and the judges will be the Rev. F. C. Lambert and W. H. Rogers.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents were made between February 6 and February 11:—

MOUNTS.—No. 2,362. "Improvements in photograph and card mounts." W. P. Thompson, 6, Lord Street, Liverpool.

FRAME BRACKET.—No. 2,855. Folding frame to attach to ordinary gas brackets for holding photographic printing frames." W. Horseman, 25, Florence Road, Stroud Green, London.

SHUTTERS.—No. 2,874. "Improvements in or relating to photographic shutters." A. J. Boulton, 111, Hatton Garden, London, for Alfred Lippert, Germany.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

PRINTING FRAMES.—No. 6,483, 1904. A frame for printing from negative on to paper lengthwise, crosswise, etc. The frame has all round it a broad margin, *a*, that is to say, it is relatively wide; and has at each corner a raised portion or block, *b*, forming two crossways across the centre of the frame, in which the removable back, which supports the paper, lies. On two of the opposite angles or raised portions, the spring holding bars, *c*, are hinged, and at the other angles the fastening staples, *e*, are disposed angularly, to receive the end of the holding spring bars, and they are so arranged that each spring bar will move

under each of the staples or holders at will, and therefore, whether the back be laid across in one direction or in the other, the spring bars can be moved across one way or the other to hold and press upon the back. The back has on it a projecting metal ledge, flange, or other equivalent projections, which is or are adapted to fit in corresponding grooves in the frame edge, and when in place this holds the back firmly in position—that is to say, the back cannot move when the hinged flap portion is raised to examine the print, or at any time. W. L. Parkinson, 3a, Imperial Chambers, Dale Street, Liverpool.

FLASHLIGHT.—No. 27,466. Protection is claimed for a flashlight cartridge, the case of which is aluminium, or copper-coated aluminium, from .1 to .3 millimetres in thickness, which metal, in burning, produces a light of great intensity. Hans Lüttke, Paul Arndt, and Ernst Leopold, 8, Tollstrasse, Wandsbek, Germany.

CAMERAS.—No. 5,204, 1904. A camera for ordinary and colour-photography (improved from Patent No. 26,873, 1902), in which the colour filters are carried by a pivoted segment, formed in two parts, which can be fixed in position for photographing in colours and separated for ordinary work. The change of filters when photographing in colours is affected at the same time and by the same pressure on the pneumatic ball as the change mechanism of the plates. Jean Frachebourg, 5, Rue Grange Batelière, Paris.

HAND CAMERAS.—No. 5,327, 1904. A reflector camera in which the mirror is pulled down into the reflecting position by a slotted bar instead of by cords. It is raised for exposure by a lever drawn down by a spring at one end, the other bearing up against the mirror. In front of the mirror a shutter or board or wing of light material is mounted. On a support, preferably on a board in front of the mirror, is mounted a shutter or wing which is made of light material. An aperture is cut in the board, through which the light from the lens passes. The shutter is placed so that when the mirror is at the top of the shutter it covers the aperture. When the mirror is being set, and when it has got into such a position that it will intercept the lens rays, it is caused to remove the shutter from the aperture. When the mirror is released to give the exposure, it ascends past the open aperture. It then comes in contact with the shutter and replaces it in its first position, covering the aperture and ending the exposure. S. D. McKellen, 14, Market Place, Manchester.

New Books.

"Die Theorie der Optischen Instrumenten." Band I. Die Bilderzeugung in Optischen Instrumenten vom Standpunkte der geometrischen Optik. Edited by M. von Rohr. Published by Julius Springer, Berlin.

This work, which is the first volume of a series dealing with the theory of optical instruments, is practically a revision of Dr. Czapski's "Theorie der Optischen Instrumente nach Abbe," published in 1893, and, as we learn from the preface, written by Dr. Czapski, he found it impossible to personally revise this, and thus sought the collaboration of the scientific staff of the Carl Zeiss Optical Factory, P. Culman, A. König, F. Löwe, H. Siedentopf, and E. Wandersleb; and Dr. von Rohr has edited this new book. One of the main advantages that has accrued through this collaboration is, of course, that individual subjects are treated by those experts who are particularly engaged in the practical part thereof, and thus, without overlapping, one avoids that one-sided view which must necessarily result, when one man deals with every subject.

The book is divided into ten chapters, which naturally fall into three groups, the first of which comprises Chapter I., "Die Berechtigung einer Geometrischen Optik" (the foundation of geometrical optics), by Dr. H. Siedentopf; Chapter III., "Die Geometrische Theorie der Optischen Abbildung nach E. Abbe" (the geometrical theory of optical image formation, according to E. Abbe), by Dr. E. Wandersleb; Chapter IV., "Die Realisierung der Optischen Abbildung" (the realisation of the optical image formation), by Dr. P. Culman; and Chapter VIII., "Die Prismen und Prismensysteme" (prisms and systems of prisms), by Dr. F. Löwe. These practically deal with the theories of reflection and refraction.

The second group consists of Chapters V., VI., and IX., which are "Die Theorie der Sphärischen Aberrationen" (the theory of spherical aberrations), "Die Theorie der Chromatischen Aberrationen" (the theory of chromatic aberrations), and "Die Strahlenbegrenzung in

Optischen Systemen" (the limitation of the rays in optical systems), by Drs. A. H. König and von Rohr respectively. The fifth chapter gives us, for the first time, a complete working of Abbe's invariant method of treating all the ten aberrations according to Seidel, and this for the first time enables one to see how much further Abbe's method goes than Seidel's. The titles of Chapters VI. and IX. speak for themselves. Chapter II., "Die Durchrechnungsformeln" (the formulæ of calculation), by Drs. König and von Rohr, and Chapter VII., "Berechnung Optischer Systeme auf Grund der Theorie der Aberrationen" (the calculation of optical systems based on the theory of the aberrations), by Dr. König, will be of considerable value to the practical optician, as therein are worked out examples of the calculations of a corrected system and the curvature of the glasses and the distances of separation of the lenses, and the diaphragm positions are fully discussed. Chapter X. completes this group, and is devoted by Dr. von Rohr to "Die Strahlenvermittlung durch Optische Systeme," which deals with the photometric relations of an optical system.

The value of this book is considerably enhanced by the extremely complete subject index and register of authors, and their works which are referred to or quoted in the text.

"The Inventor's Guide." By Jas. Roberts, M.A., LL.B. Published by John Murray, 50A, Albemarle Street, W. Price 2s. 6d.

"The Inventor's Adviser and Manufacturers' Handbook to Patents, Designs, and Trade Marks." By Reginald Haddan. Published by Harrison and Sons, 45, Pall Mall, W. Price 5s.

The first of these books is a simple, succinct explanation of the law and rules governing the Grant of Patents, and is founded on the more complete and comprehensive work by the same author, entitled "The Grant and Validity of British Patents for Inventions," and has been written with special regard to the new practices involved by the 1902 Act, which came into force on January 1 of this year. The author first defines what is a patent, differentiates briefly between valid and invalid patents and patentable inventions, and then enlarges on these terms; so that, after a careful perusal, one has a very clear sketch of what to do and what not to do, and we have no hesitation in saying that a careful study of the first three chapters alone would save would-be patentees considerable trouble and, at times, expense. The instructions for filling up and filing the necessary papers are exceptionally clear; as is also the effect of the new Act, and the instructions as to opposing patents, how to treat infringements, etc. The work is completed by a reprint of the 1902 Act, the new rules, and a copious index.

Mr. Haddan's book is a much more comprehensive work than the above, and deals with trade-marks and designs as well as patents, but it also has been brought up to date and partly rewritten, particularly with regard to the new procedure. Not the least valuable part of the book is the copious references to contested cases, and the very complete but succinct summary of the facts as to the granting of foreign and colonial patents. In a useful appendix too are the forms of applications for patents in the various languages. The trade-mark and designs sections are also complete and clear, and by the aid of the index, which is very elaborate, even the most ignorant would be able to find out any information that he may desire.

THE next meeting of the R.P.S. will be on Tuesday, February 28. Messrs. W. F. Ferguson, K.C., M.A., F.R.P.S., and B. F. Howard, A.M.I.E.E., F.R.P.S., will lecture on "Control of the Development Factor at Various Temperatures."

New Materials.

Collodion Lantern Emulsion. Sold by Penrose and Co., 109, Faringdon Road, London, E.C.

A brand of collodion emulsion is now being supplied by Messrs. Penrose specially for the making of lantern slides, transparencies, and ferrotypes. The emulsion can be exposed either wet or dry, and develops quickly. Glass plates should be cleaned in acid, slightly polished, and, after receiving a thin substratum, coated with the emulsion in the usual way. They dry very quickly, and the amateur worker will find no difficulty in preparing a number if he sets aside a good-sized box in which to shield them from dust during drying. The collodion works a good deal softer than wet collodion, and yields slides of the necessary softness and richness in the shadows. Nevertheless, by cleaning off all fog from the ground of the slide from a line drawing, the lines can be intensified to any required vigour. The usual toning agents can be applied to the slides for the production of warm tones. The price of the Penrose emulsion is 25s. per quart, and not less than a pint bottle, 13s. 6d., is supplied. Lower prices can be quoted on larger quantities.

CATALOGUES AND TRADE NOTICES.

The Thornton-Pickard Co. announce that their 1905 catalogue is now ready for distribution, and will be sent post free to all applicants. It contains particulars of the Company's new introductions, notable among which are:—Royal Time and Inst. Shutter: a new patented shutter of the roller-blind type, with all working parts inside the shutter box. Two-shutter Camera: a special pattern of the half-plate "Imperial Triple Extension" set fitted with time and instantaneous shutter in front and focal plane shutter built in the camera body; complete outfit with two shutters. Special Ruby Camera: a camera set of the well-known "Ruby" pattern at a popular price; sizes, quarter-plate to 10 by 8. Crown Outfits: an outfit of moderate price, combining many high-class features, suitable for stereoscopic and general work; half-plate and whole-plate sizes; double and triple extension models. Rotator Hand Camera: a box-form magazine hand camera to carry twelve plates, fitted with self-capping time and instantaneous roller-blind shutter, giving exposures from "time" up to one-ninetieth of a second.

Messrs. W. Watson and Sons, of High Holborn, have opened a branch establishment at No. 2, Easy Row, Birmingham, under the management of Mr. Glover, who has been with them for the last eight years. A full stock of their photographic apparatus and specialties in microscopes, X-ray, and high-frequency apparatus, etc. will be kept in the Midland capital.

Messrs. T. Naylor and Sons, makers of photographic apparatus, have removed from Greek Street to 13, Hanbury Works, Hanbury Street, Tottenham Court Road, W.C.

The monthly Elge list of cinematograph films reaches us from Messrs. Gaumont and Co., Cecil Court, London, W.C., and contains details of some of the trick sensation subjects now so popular.

Messrs. J. Winton Mason, 21, St. Peter's Street, Ipswich, send us a circular of prices at which they offer glazed P.O.P. postcards in large or small quantities at favourable prices.

QUICK WORK.—Messrs. P. Lankester and Co., of Tunbridge Wells, send us two postcards taken by flashlight at a Tariff Reform meeting. The exposures were made at 8.10 p.m., and the prints were delivered to the chairman at 9.30 by express letter post.

FORTHCOMING EXHIBITIONS.

February 15-March 15.—International Exhibition Artistic Photographs, Vienna. Hon. Secretary, Dr. Reiniger, Camera Club, Largerplatz No. 3, Vienna III., 3.

February 21-March 7.—Glasgow Southern Photographic Association. Hon. Secretary, W. A. Frame, 23, Bank Street, Hillhead, Glasgow.

February 24-March 4.—Northampton Photographic Society. Entries close February 14; for pictures, February 17. Hon. Secretary, E. J. Felce, 83, Adam's Avenue, Northampton.

February 25-March 4.—Birmingham Photographic Society. Hon. Secretary, Lewis Lloyd, Norwich Union Chambers, Congreave Street, Birmingham.

February 25-March 11.—Edinburgh Photographic Society. Entries close February 11; for pictures, February 15. Hon. Secretary, J. S. McCulloch, 3a, North Saint David Street, Edinburgh.

March 4-11.—South London Photographic Society. Hon. Secretary, H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 7-8.—G.E.R. Mechanics' Institution, Stratford, E. Hon. Secretary, A. Woolford, 16, Grove Green Road, Leytonstone, E.

March 14-17.—Brentford Photographic Society. Hon. Secretary, F. H. Read, Ferndale, Clifden Road, Brentford.

March 16-30.—International Photographic Exhibition, Earl's Court. The Organising Managers, 119-125, Finsbury Pavement, London, E.C.

March 20-25.—The Cripplegate Photographic Society. Hon. Secretary, John B. Parnham.

March 27-April 1.—Leicester and Leicestershire Photographic Society. Entries close on March 20, 1905. Secretary, R. Warden Harvey, Oriental Cafe, Market Place, Leicester.

March 30-April 3.—Chiswick Camera Club. H. Gentry, 39, Fairfax Road, Chiswick.

April.—International Exhibition, Genoa. Sec. Gen., Piazza Fontane Marose 18, Genoa.

April 3-15.—Photographic Society of Ireland. Hon. Secretary, R. Benson, 35, Molesworth Street, Dublin.

April 4-6.—Wallington Camera Club. Hon. Secretary, J. W. Corbett, Nithsdale, Onslow Gardens, Wallington.

April 5-8.—Nottingham Camera Club. Hon. Secretary, S. W. B. Vines, 102, Woodborough Road, Nottingham.

April 7-15.—Photographic Trade Exhibition, Portman Rooms, Baker Street, London, W. Manager Pictorial Section, W. Selfe, 70, Paragon Road, Hackney, London, N.E.

April 7-May 8.—International Artistic Exhibition, Berlin. Director, Herr Franz Goerke, Maassenstrasse 32, Berlin, W.

May 1-31.—International Exhibition of Photographic Pictures Postcards, concurrently with the 10th Salon. M. le Secrétaire Général du Photo Club de Paris, 44, Rue des Mathurins, Paris.

May 9-10.—Ballarat Camera Club. Hon. Secretary, G. Montgomery, 201, Sturt Street, Ballarat.

May 10 to June 19.—Salon of the Photo Club de Paris. Entries close March 1, and pictures must arrive by April 10. Secretary, Paul Bourgeois, 44, Rue des Mathurins, Paris.

June.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

March 31.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Limited, Ilford, E.

September.—Kodak. £400 in prizes for results on Kodak products. Kodak, Ltd., 57-61, Clerkenwell Road, London, E.C.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

Feb.	Name of Society.	Subject

2.....	Watford Camera Club	Conversation.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

A SMOKING concert was held on Thursday, February 16, in place of the usual supper, Mr. T. K. Grant in the chair. The musical arrangements, for which the chairman had kindly made himself responsible, kept a goodly company entertained until a late hour, and the thanks of the meeting was voted to those who by their interest and talent had contributed to the enjoyment of the occasion. The impending resignation of Mr. R. J. Kindon from the secretaryship brought forth friendly protest, but the appointment of a successor who will take the same active and enthusiastic share in the fortunes of the L. and P. is a task which must be accomplished within the next few months.

BOLTON AMATEUR PHOTOGRAPHIC SOCIETY

A PAPER on "The Trimming and Mounting of Prints" was read at this Society's meeting on February 8, by Mr. H. Mills. Commenting on the fact that the proportions of photographic plates are not those best adapted to the requirements of pictorial composition, the lecturer advocated a judicious use of the trimming knife. As regards mounting, Mr. Mills deprecated the general practice of placing the print centrally on the mount. Because of a well-known optical illusion a print so placed appears to be nearer the bottom than the top of the mount, and usually presents a top-heavy appearance. The placing of the print should always be carried out in such a way as to assist the composition of the picture, and the colour of the mount should in all cases be selected to harmonise with the tone of the print. The lecturer recommended home-made mounts cut from papers of the "nature series" description in preference to stock mounts of the "paste on" and "slip on" types. While admitting that the practice of masking a white

border round the print or ruling white lines on the mount is not conducive to artistic effect, the lecturer stated that sometimes the effect of a picture may be heightened by dark crayon lines round the print. A point to be borne in mind is that black and white prints should not be mounted on coloured mounts, but on mounts of some neutral (preferably grey) tint, the reason for this being that there is no colour in the print to harmonise or contrast with a coloured mount.

WHITBY CAMERA CLUB

A DEMONSTRATION on "The Making of Enlarged Negatives," by Mr. Woodhouse Parkinson, the honorary secretary, was given before the members of this Society on Friday last. The lecturer explained that the value of enlarged negatives lay in the fact that from them could be made prints by either the platinotype process, or the various chromate processes, carbon, gum-bichromate, artigue, etc., which could not be compassed by lantern enlargements in the same way as bromide enlargements. A great deal of control could be exercised, and pictorial effects attained. There were two methods, one to make a diapositive by contact, and enlarge from that, the other to make a full-size diapositive and a large negative by contact. He preferred the former way, and believed it was more generally employed. For the diapositive, the best results were to be obtained from a carbon transparency. An ordinary negative plate might be used, or, better still, a plate prepared with lantern slide emulsion. But carbon, if carefully worked, gave greater fineness of detail. Having got the diapositive, some suitable apparatus must be used for projecting the enlarged image on to the negative plate. A lantern as used in bromide enlarging was suitable, but Mr. Parkinson used a 15 x 12 daylight enlarger, in conjunction with a camera, and illuminated the diapositive with magnesium ribbon. For the enlarged negative he used Rotograph negative paper, and developed with rodinal.

ABERDEEN PHOTOGRAPHIC ASSOCIATION.—The annual "at home" in connection with the Aberdeen Photographic Association was held on Monday last in Kennaway's Rooms, Aberdeen. Mr. James S. Anderson, president of the Association, presided over a large attendance of the members and friends.

HARROGATE CAMERA CLUB. — On Thursday evening last a demonstration on printing papers was given by Mr. C. H. L. Jackson in the Builders' Exchange, Harrogate. Mr. Jackson also dealt with Rotograph negative paper, and the many advantages in using this in place of glass plates for making enlarged negatives for carbon printing, or when several large prints are required, was very ably illustrated. By making an enlarged positive all necessary retouching can be done on the paper side of this, and accurately judged. From this positive an enlarged negative is made by contact, and further retouching can again be done on the white paper back. If the final print is required in carbon, printing may be done from the reverse side of the negative, thus avoiding double transfer.

MR. HARRY DE WINDT, the well-known explorer, whose remarkable journey from Paris to New York overland created such interest some eighteen months ago, is about to undertake another expedition, this time through the little-known parts of Eastern Europe, in the interest of Messrs. George Newnes. A photographer of the Urban Bioscope Company will accompany Mr. de Windt to obtain living pictures. Articles on the expedition will appear in the "Wide World Magazine," and a series of letters in the "Westminster Gazette."

Commercial & Legal Intelligence

GRIANAN NA NGARDHEAL, LIMITED.—Registered February 14, with a capital of £500 in £1 shares, for the purpose of carrying on business as printers, booksellers, photographers, etc. Registered office: 59, Patrick Street, Cork.

PHOTO AND ART PRINTING COMPANY, LTD.—Registered February 3. Capital £27,500, in £1 shares (7,500 Preference). Objects: To carry on the business of photographers, photographic and general printers, lithographers, artists, engravers, modellers, publishers, stationers, paper makers, chemists, booksellers, bookbinders, etc. No initial public issue. Registered office, 122, Victoria Street, S.W.

AN Unsuccessful Claim.—At the Greenwich County Court, on Friday last, John Compton Lawton, trading as the Salisbury Electrical Engineering Co., at 141 and 143, New Kent Road, and late of 178, High Road, Le, sued Francois de P. Romani, trading as the Souviner Miniature Co., at 51, Ermine Road, Ladywell, for £19, for two arc lamps supplied and fitted. Mr. Parsley, plaintiff's manager, said that he went to the defendant's photographic studio, and he gave him the order for the lamps. He denied that defendant stipulated that they should each be of 1,500 candle power, suitable for printing purposes. For the defence, Mr. Doughty called the defendant and several witnesses who were present when the order was given. They swore that the lamps for printing purposes must be 1,500 candle power, and that Mr. Parsley was informed for what purpose they were required. Mr. Charles Rawlings, of the firm of Rawlings Bros., Ltd., electrical engineers, of Blackheath Village, called as an expert, said that he had inspected the lamps, and they were about 500 candle power each, and were not capable of printing photographs. His Honour said that it was clear that the plaintiff knew the purpose for which the lamps were required, and gave a verdict for the defendant with costs.

ALLEGED Photographic Fraud.—At the Clerkenwell Police Court, on February 18, Richard Lewis was charged with obtaining £1 12s. by means of false pretences from Charles Baker, draper of Gernault Place, Clerkenwell. It appeared that on February 9 the prisoner called on the prosecutor, and asked him if he would like his premises photographed. He said he was a canvasser for A. and G. Taylor, of Regent Street, W. The prosecutor agreed to have his shop photographed, and to purchase copies to the value of 12s. 6d. The prosecutor paid the prisoner 5s. deposit; the latter agreed to call the following day, and take a photograph of the premises. He fulfilled this part of the contract. On February 11 he called again and asked Mr. Baker to change a cheque for £1 7s. Not receiving the photographs, the prosecutor visited the premises of A. and G. Taylor, and from what he was told there, he put the matter in the hands of the police. It was ascertained that prisoner had been in the employ of Messrs. A. and G. Taylor, but left their service on February 4. When arrested by Detective-sergeant Cunningham, the prisoner said, "I have been on the drink lately and I am a fool." He further said, "I have an account at the London and Joint Stock Bank, and a balance of 14s 9d." Mr. Bros remanded the accused.

CATFORD and Forest Hill Photographic Society.—In the annual competition of the Society the awards were as follows:—President's prize for excursion pictures, F. H. Fenton. Other prints.—H. Solley 1, J. Mason 2, G. T. R. Collis 3. Mr. Pearce's prize for enlargements.—H. Solley 1, F. H. Fenton 2. Mr. Hart's prize for lantern slides.—H. Solley 1, Dawes 2, Rev. H. O. Fenton 3.

News and Notes.

GLASGOW Photographer Poisoned.—The death is reported as the result of drinking cyanide of potassium of Mr. Thomas William Steven, photographer, South Portland Street, Glasgow.

FELLOWSHIP of the Royal Photographic Society.—The following members have been elected Fellows of the Society:—Miss S. A. Acland, Mr. C. Thurston Holland, M.R.C.S., Mr. A. H. Starnes, Mr. T. K. Grant, Mr. Otto Fulton, Mr. Furley Lewis, Mr. F. J. Mortimer.

RAILWAY Lantern Slides.—Lantern slides showing places of interest on the London and North-Western Line are available for the purpose of illustrating lectures, etc., and a list of slides can be obtained on application to Mr. R. Turnbull, superintendent of the line, Euston Station, N.W. Slides have also been made of the subjects shown on the company's pictorial postcards, which practically show every phase of past and present railway working. It is thus possible for applicants to ascertain beforehand the nature of the slides. No charge is made by the company for the use of the slides, but they must be returned day following exhibition.

DURING the recess Sir Benjamin Stone, M.P., whose collection of photographs attracted so much attention at the St. Louis Exhibition, has been busy with his camera, the result being some notable additions to his permanent pictorial record of current national life preserved at the British Museum. Amongst his latest negatives are two reproducing with remarkable fidelity of detail the obverse and reverse of the new Great Seal of England, which had to be made in consequence of the King's accession. One side is photographed so as to show the design in relief, although it is actually a deep sunk intaglio die; and the other is photographed so as to show the intaglio effect of the die. Sir Benjamin Stone has also enriched his collection recently with some excellent pictures of Algerian scenery obtained while visiting the district some months ago.

THE Cyko Competition.—The awards in this competition, arranged by Messrs. John J. Griffin and Sons, Ltd., have now been made, and the following are the names of those fortunate enough to secure prizes. Class "A" (Guinea Cyko): 1st, S. E. Verstage, Meadrow, Godalming; 2nd, H. Featherstone, 66, Park Street Southwark, S.E.; 3rd, J. MacFarlane, Sandringham, Stapleton Road, Bristol; and W. C. Hope, St. Columb, Cornwall; A. H. Verstage, Park Villa, Godalming; H. D. King, 34, Beachcroft Avenue, Southall, Middlesex; F. Fletcher, Bridge Terrace, Thornton, Lancs.; J. A. Allison, Primrose Lodge, Manghold, Isle of Man; H. Scott Beauchamp, 42, Nunner Fields, Canterbury; J. D. A. Telford, 278, Dewsbury Road, Leeds; A. T. Millner, "Deene," Tooting Bec Road, Streatham, S.W.; R. K. Ludlam, 400, Heath Terrace, West Bromwich, near Birmingham; A. Wallhouser, 24, Delamere Crescent, Paddington, W.; Miss Alice M. G. Lloyd, "Deene," Tooting Bec Road, Streatham; W. A. Gastin, Main Street, Limavady, Co. Derry; W. E. Massingham, 77, Stokes Croft, Bristol. Class "B" (Pocket Cyko): 1st, C. P. Woodward, 51, Beach Farm Road, Southsea; 2nd, C. B. Donkin, Penmore House, Haslarn, near Chesterfield; 3rd, R. B. Ewbank, Bolton Rectory, Mealsgate, Carlisle; 4th, Miss Galtsmith, 6, St. Deny's Road, Southampton; and J. M. Jackson, East Kirklands, Hamilton, N.B.; F. R. Gulline, 16, Falconer Street, Newcastle-on-Tyne; F. D. Fearon, 12, Waldeck Road, West Ealing; A. Collins, 141, Alexandra Road, Croydon.

COMPLIMENTARY Dinner to Mr. A. W. W. Bartlett.—Mr. A. W. W. Bartlett, the late Secretary of the Royal Photographic Society was entertained by several of his friends at a dinner held at the Hôtel

d'Italie on the 16th inst. Among those present were J. C. S. Mummery, who occupied the chair, P. Bale Rider, who was responsible for the arrangements, W. G. Holman, J. H. Avery, Furlley Lewis, P. R. Salmon, Leslie Clift, C. H. Oakden, G. Lamley, J. McIntosh, W. E. Southcombe May, L. Selby, J. Brown, W. H. Willshire, J. R. Lynch, and several others. At the conclusion of the dinner Mr. Bartlett was presented with a handsome dressing bag, and the remainder of the evening given up to speeches, songs, music, etc.

THE prospectus of the pictorial section of the fourth Photographic Trade Exhibition, to be held in the Portman Rooms, Baker Street, London, W., from April 7 to 15, 1905, inclusive, has been sent us. The classes (open to all) consist of (a) landscape, seascape, and river subjects; (b) portraiture and figure studies; (c) architecture; (d) animals, still life, scientific, and any subject not included in a, b, c; (e) lantern slides (sets of 4); and the awards will be silver and bronze plaques in each class, and a gold medal for the best exhibit in the pictorial section. Mr. H. W. Bennett, F.R.P.S., is the judge, and exhibits must be sent to the Portman Rooms, Baker Street, London, W., not earlier than Saturday, April 1, nor later than Tuesday, April 4. Entry forms must be returned by March 20 to the Organising Manager, Walter Selfe, 70, Paragon Road, Hackney, London, N.E.

HIGH POWER MICROSCOPY.—The Friday evening lecture at the Royal Institution last week was given by Mr. J. W. Gordon, who discussed "High Power Microscopy." Sir James Crichton Browne was in the chair, and the audience included Lord Rosse, Lord Rayleigh, Mr. Justice Buckley, Sir Andrew Noble, and Sir William Crookes. Considering first the preparation of a microscopic object for exhibition under suitable conditions of illumination, the lecturer referred to the use of cross-lighting or "dark ground illumination," and in particular to Dr. Siedentopf's application of this principle to the exhibition of ultra-microscopic particles. In ruby glass, for instance, the colour was due to diffused particles of gold, so minute as to be beyond the imaging power of any microscope; yet by the aid of cross-lighting they could be rendered visible as diffraction discs, precisely as stars were visible in the firmament. The lecturer next mentioned some experiments, which were suggested by the paper of Lord Rayleigh's, but were still in a very early stage, undertaken with the view of utilising diffracted light to illuminate the object, and went on to refer to the fact, which was still imperfectly understood though pointed out by Helmholtz over thirty years ago, that the limit of useful microscopic power in a high-power objective was reached when the lens of the objective was of such focal length that its diameter was rather less than the diameter of the pupil of the eye. Beyond this limit increased scale was best gained by viewing the image formed by the objective through an eye-lens of high magnifying power. But this expedient carried with it the difficulty that the emergent pencil of light became extremely small—often no more than one-thousandth of an inch in diameter with microscopes of high power—and in consequence microscopists had settled down to the belief that for visual work no more than 1,500 to 2,000 magnification could be usefully employed. In fact, 400 to 600 diameters would more adequately represent the average scale of good critical work hitherto. A contrivance recently introduced to meet this difficulty consisted of a screen of ground glass placed in the microscope tube at the point where the image was formed; by this the incident pencil of light, however narrow, was broken up and thrown off again as a broad pencil, which could be submitted to high magnifying powers without deterioration. Hence by using a second microscope instead of the usual eye-lens enormous magnifications, hitherto unattempted, could be secured. It was necessary to keep the screen in motion, else its grain would become visible to such an extent as wholly to impair the details of the picture.

Correspondence.

BLISTERS ON BROMIDES.

To the Editors.

Gentleman,—As an old pupil of Mr. Harold Baker, I cannot refrain from writing as regards his article in this week's issue on "Blisters on Bromide Paper." I had the same trouble last Christmas, just when time was very valuable, and found an absolute preventative in a bath of fairly strong salt and water immediately after fixing and before washing. A simple, effective, and cheap method.—Faithfully yours,

W. E. DIXON, Manager.

Brighthouse Photographic Co., Ltd., Briggate, Brighthouse.

THE PERMANENCE OF TONED BROMIDES.

To the Editors.

Gentlemen,—The formula of Messrs. Lumiere and Seyewetz for toning bromides with lead ferrieyanide and cobalt chloride, reminds us of some experiments we tried with these salts some ten or twelve years ago.

We obtained very fine green, but a few months exposure to light and air utterly spoilt the prints, so that we considered the formula of no practical use.

After an exhaustive series of experiments spread over some years, we have come to the conclusion that brown, from an orange to warm black, are the only colours which can be called really permanent. Of course we do not mean that the last word has been said on toning of bromides, but in the course of our experiments we tried pretty well all of the methods which have recently been published in various formulae.—Yours faithfully,

WELLS AND CO.

Avenue Road, Southgate, February 13.

THE SEARS HIGH-LIGHT PROCESS.

To the Editors.

Gentlemen,—Re your description of Sears' Process. In 1885 Mr. J. W. Geddes, then of Messrs. Waterlow, Ltd., was making use of this so-called new process, and we have also been doing so, using negative or transparency as required, for twenty years.—Yours faithfully,

A. WOOD AND SON.

10, St. Bernard's Row, Stockbridge, Edinburgh.

THE FIRST AMERICAN SALON AND THE PHOTO-SECESSION.

To the Editors.

Gentlemen,—The attitude of the "Photo-Secession" toward the First American Salon at New York has excited much adverse criticism, and it is to be presumed that the subject is of sufficient interest to warrant setting forth some of the reasons why the "Photo-Secession" took the stand it did, and the ultimate justification of its course.

You will remember that Mr. Alfred Stieglitz, Director of the "Photo-Secession," issued a letter to the Press, appearing in the August number of most of the American magazines, in which he announced that the Salon in New York "will be of such a type or character that neither I nor the 'Photo-Secession' can have any connection with it, or be represented therein." As a result of this announcement there came a storm of denunciation that included everything from the "Photo-Secession" and Mr. Stieglitz to the grammar and diction of the letter and the supposed prophetic inclinations of its writer.

The fact that the management of the First American Salon at New York had, from the first associated itself with influences

opposed to the "Photo-Secession," such opposition being due to circumstances that have no bearing on the point in question—that while every photographic interest but one in this country and Europe was being propitiated by the Committee, every opportunity to sneer at and privately and publicly condemn the "Photo-Secession," was taken advantage of, would surely have justified the "Photo-Secession" in deciding to have nothing to do with the Salon, and in even publicly announcing the decision with considerable more force than was done, yet these were not the reasons why it was decided to hold aloof from the exhibition.

It had come to our knowledge, and in such a decided way that it could not be gainsaid, that the management of the Salon was not pursuing a course calculated to guarantee that fairness and freedom from prejudice necessary to the holding of an exhibition of photographs that would be of any value to the advancement of pictorial photography. We learned that the Europeans had been told their exhibitions would be *hors concours*, in spite of the assurance that all prints must pass the jury, an assurance vaunted with an insistence that was from the very first an insinuation against the "Photo-Secession." It was felt that there was a lack of sincerity, a lack of purpose, and a lack of ability that boded ill for photography and as the "Photo-Secession" stands, not for the "Photo-Secession;" not for Stieglitz; not for its fellows; nor yet for its associates, but for photography, the decision was against the Salon.

When we learned that the letters Mr. Hartmann sent to the Europeans inviting them to send exhibits *hors concours* were written and mailed under the direction of the Metropolitan Camera Club, Mr. Hartmann simply signing the letters at the club in the presence of Mr. Roland Rood; when Mr. Curtis Bell, President of the Salon, told Mr. Rood, who was representing the "American Amateur Photographer," that he and another would select certain prints to be submitted to the jury; when we saw the catalogue and noted the suspicious abundance of names previously known through minor exhibitions and competitions, and when we saw the Salon itself, we felt we were justified in the stand we took.

But not so the photographers at large and the general public. Mr. Bell repudiated Mr. Hartmann and his letters. Mr. Bell wrote to Mr. Rood that the plan he had mentioned had been changed and all prints would go before the jury. The minor photographers were lauded by the critics as the true pictorialists, and the salon was hailed as the exemplification of photographic art; the raising of photography from the Slough of Despond; the dawning of a new era! And the photographers at large and the public believed.

Now, Mr. Frederick W. Kost, A.N.A., a member of the jury, who was of the few that served and who got the jury together for the Salon, says that he informed Mr. Curtis Bell, President of the First American Salon at New York, that it would be impossible for the jury to look over so many pictures, and Mr. Bell selected the number the jury passed upon, which did not exceed 1,800 prints! Think of it! Seven thousand two hundred prints passed upon by Curtis Bell and eighteen hundred by the jury of artists!

Does the "Photo-Secession" need any further justification of its attitude? No! Not even the further statement of Mr. F. W. Kost, member of the jury, that the jury did not consider any of the photographs "works of art," and that they all were surprised to find so much ignorance of all art principles so generally displayed.

I will refrain from comment on the position of the management of the Salon.—Yours truly,
HARRY C. RUBINCAM.
206, 207, 208, Century Buildings, Seventeenth and Stout Streets,
Denver, Col., U.S.A.

[We publish Mr. Rubincam's letter *minus* certain personal allegations against Mr. Bell which appear to us irrelevant. For the rest we confess that certain of his statements seem to us logically, if not grammatically, obscure. Probably the position is capable of a perfectly natural explanation, and we shall be agreeable to hearing Mr. Bell's side of the controversy.—EDS. B.J.P.]

Answers to Correspondents.

- * * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- * * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.
- * * * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

Isaac Perloff, 188, Commercial Road, London, E. Photograph of Mr. P. Orloff, famous Russian Actor.
E. O. Parkin, 58, Wilkinson Street, Sheffield. Seven Photographs of Bishop Pearson.

- J. W. BARNES.—We believe Raines and Co., Ealing, W.
- A. B. C.—Your queries were answered last week. See p. 139.
- J. W. SMITH (York).—Messrs. Richeford, Snow Hill, London, E.C.
- A. L. (Penarth).—We do not see how we can help you. Surely you know your public better than we do.
- MARK E. MITCHELL AND Co.—Penrose and Co., 109, Farringdon Road, E.C.
- S. W. OWEN.—We believe the address is: A. G. Snow, 84, St. Andrew's Road, Walthamstow.
- C. M.—We cannot see that you have any claim whatever, nor do we see why anybody should feel aggrieved, the team was wanted not ornamental, but with useful appendages.
- P. L. AND Co.—(1 and 2) None that we know of. (3) Not in English. There may be some in French or German, but your question is not very clear. We presume you mean negatives by "photographic plates." If you will explain further we will look the matter up.
- O. E. CHALLIS.—The transparency is very suitable for enlargement up to about 12 x 10; for greater enlargement it should be flatter. Use twice the weight of crystallised sulphite. Crystalline potass. carbonate is very variable in composition. You had better get the "dry" (anhydrous) carbonate.
- THE P.P.A.—Will you kindly give me following information through your correspondents column: How to become a member of the Photographic Professional Association, or could you oblige me with the address of secretary of same and terms of subscription?—T. F. P.
Address the Hon. Sec.: Alfred Ellis, Honorary Secretary 51, Baker Street, London, W.
- BOOK ON STUDIO WORK.—Will you kindly inform me what is the most useful book on "Studio Photography," published at a reasonable price, embracing chiefly the lighting of the studio and the artistic lighting of the sitter?—EDINOL.
"The Lighting in Photographic Studios," by P. O. Duchochois, 1s. "The Pose in Portraiture," No. 1 of "The Photo-Miniature," 6d. We gave a list of other books on page 29 of our issue of January 13 last.
- COPYRIGHT.—(1) Postcard is brought to studio marked "Copyright," from which enlargement is required. Are we infringing if we make it? (2) Does the printing of "copyright" upon photo or print ensure its being copyright.—TALBA.
(1) Certainly, unless your customer is owner of the copyright. (2) A photograph is copyright as soon as it is made.

Official registration of the copyright at Stationers' Hall is necessary to legally sustain it in any action.

BOOK ON COLOURING.—Will you kindly give me the name and publisher of some all-round book on colouring photographs? I have read Johnson's "Art of Retouching and Colouring," but should like something more extensive.—**COLOURING.**

There is a little book, "The Photographic Colourist," by J. W. Neville (6d.), also No. 44 of the "Photo-Miniature," but beyond these we know of no manual except A. H. Wall's "Art of Colouring Photographs." It has been out of print for years, but you might get it by advertising.

FREEZING MIXTURE.—Would you kindly give, at your convenience, in an early issue of the B.J., a reliable formula for making a small quantity of ice? Have tried the sal ammoniac and salt-petre formula mentioned in the "Almanac" of 1904. Temperature of this mixture falls to 15 deg., but will not remain permanently at that temperature, and soon rises again to 36 deg. or 40 deg. I require a mixture that will remain at a low temperature for several hours.—**FREEZE.**

The best freezing mixture is crystallised sulphate of soda and about half its weight of hydrochloric acid, but no mixture remains cold indefinitely. Ice and salt, we should think, is the only mixture of any practical use to you.

BERNARD T. HUGH.—Without seeing the apparatus it is not easy to say, but we consider the time too short for complete washing. We should not place confidence in the test of a single negative. Your best course is to make a series of tests by the nitrate of silver method, which is easily applied as follows: Soak the washed negative for ten minutes in clean water and place a little of the liquid in a glass test tube, pouring a like amount of plain water into a similar tube. Add now a few drops of 10 per cent. solution of silver nitrate to each tube. Warm the water to be tested. It will turn yellowish if hypo is present and a very slight coloration can be observed by comparing it with the second tube.

COMBINED BATH ENLARGEMENT.—Will you please oblige me with answers to the following questions? 1. Formula for combined bath for albumised paper to give purple-brown tones. 2. What will be the distance between centre of lens and screen in photographing an object to exactly $17\frac{1}{2}$ times its diameter, using a 2 inch lens.—**MICRO.**

1. Albumen paper is not well suited to toning in a combined bath, but you can use: Soda phosphate, 15 grs.; ammonium sulphocyanide, 25 grs.; hypo, 240 grs.; water, 2 ozs.; gold chloride (dissolved in a little water and added last) 1 grain. 2. $17\frac{1}{2}$ by $2 + 2 = 37$. The rule is multiply focal length by number of times of enlargement and add one focal length thereto.

DRYING BROMIDE CARDS FLAT.—Can you oblige me with a method of drying bromide postcards flat? I have to turn out quantities of about 100 at a time. I have hardened the cards with formaline and dried with gentle heat, as they are wanted at once. They curl violently while those you see in the shops always seem to remain flat.—**H. HARRISON.**

The best plan to prevent bromide cards from curling is to place them face outwards as soon as they come from the washing water between two thin slats of wood nailed to a board, the distance between the slats being just half an inch less than the cards—that is to say, the slats must be five inches apart. This quite prevents the curling, which is due to the contraction of the gelatine in drying.

APPRENTICESHIP.—Will you be good enough to give me your idea of terms of apprenticeship for a boy and a girl about 16 years old, length of time to be bound for, what progressive wage;

whether any first year without premium, also with small premium, say £10 or £20? To give you an idea of the class of work we do, our cabinets are 25s. and £2 2s. per dozen. The boy to go through it all; the girl spotting, retouching, reception room, etc.—**PREMIUM.**

There are no regular terms, either as regards premium or time of apprenticeship. It is quite a matter of mutual arrangement between the parties concerned. The same remark applies to wages. If you are a member of the Professional Photographers' Association, we should advise you to communicate with the secretary, as he will be better informed in the matter than we must confess we are.

CATTLE.—1. Either the twin lens or a reflector camera is very suitable for animal photography. You will find the leading makes described in the "Almanac." 2. We believe Rouch largely uses a reflector camera, although Gambier Bolton in his extensive photography of animals uses nothing but a stand camera. We should advise you to use a "Unipod," i.e., a single support on which to rest the camera at the moment of exposure. It practically serves the purpose of a tripod so far as permitting short exposures, such as a quarter of a second; it is erected in a moment, and does not startle animals as does a tripod. It is easily made; but there is a commercial variety made by Newman and Guardia. 3. We think you might have a focussing scale and a large finder, fitted to an ordinary focussing half plate stand camera, and do very satisfactory work with this on a unipod, though a twin lens or reflector camera will make your operations much more certain.

HYP0 ELIMINATION.—In the "B. J. Almanac," 1905, p. 1041, I see a formula for Hypo Eliminator, and should be much obliged if you would be so kind as to furnish information on the following points:—1. Am. persulphate $2\frac{1}{2}$ grs.; car. sod. 5 grs.; water 1 oz. Is this the complete eliminator or is it to be added to the barium dioxide, etc., appearing above it? 2. Is the treatment in any way deleterious to prints? 3. Will the solutions keep, and may they be used over again? 4. How many prints will, say, 1 oz. of solution eliminate, and how long washing before and after?—**E. W. APPLETON.**

1. The formula given is the complete eliminator, and is not to be added to the barium peroxide. 2. No. 3. The solutions will keep, but it is not advisable to use over again. 4. It is impossible to answer this question, because it depends entirely upon the amount of hypo in the print; half an hour's washing before and quarter of an hour after should be sufficient.

RESTORING DAGUERREOTYPES.—I should be indebted to you if you would kindly give me the particulars of the method of restoring daguerreotypes. I have seen the formula occasionally in the JOURNAL, but have no trace of it now.—**K.**

The method is this. First remove all dust from the surface by blowing. Then treat the picture with a dilute solution of cyanide of potassium—say ten grains to the ounce of water—until the tarnish is removed. Next well wash under the tap and finish with distilled water. Dry over a spirit lamp so as to avoid drying marks. The Daguerreotype is a very delicate image, and is very easily damaged. We should advise you to experiment on two or three pictures of no value before attempting to deal with one that is prized by its owner. Many Daguerreotypes have been irretrievably ruined at the hands of novices. Your best way, we should think, would be to entrust the work to an expert who is familiar with the working of the Daguerreotype process.

STARTING IN BUSINESS.—I should be very pleased if you would answer

me the following questions:—(1) As an amateur, and being fond of photography as a hobby, do you consider it possible for me to take it up as a business, on my own or in partnership? I am able to give six months or more at an institution where I might thoroughly learn all its branches. (2) How much capital do you consider I should require to make a successful beginning?—X. Y. Z.

(1) Of course it is quite possible for you to do so. But you must bear in mind that photography as a profession requires skill as well as good business tact to work it with success. We should think your best way would be to article yourself to a professional photographer for a term, or to enter partnership in a well-established business. (2) Impossible to say, as all must necessarily depend upon the scale and style upon which you intend to begin. Also whether you have to erect a studio, etc., or take one ready for occupation. It may be anything from £100 or £500, or more.

TONING-BATH PERCENTAGES.—(1) A few weeks back you published a formula for toning C.C. paper red. Could you tell me if it is possible to obtain the pure red chalk tone with this bath? It was as follows:—Prepared chalk, $\frac{1}{2}$ oz.; gold chloride, 1 per cent. sol., 19 minims. (2) Could you tell me also the meaning of percentage as applied to chemicals? I have always understood it to mean grains to the ounce, as example: 10 per cent. sol. of bromide, 10 grains to the ounce. Is this correct, and, if not, will you please explain? (3) Could you let me know of a formula for toning C.C. paper green, like the sea, or olive-green, obtained on carbon?—CHALK.

(1) The best bath for red chalk tones is: Uranium nitrate, 1 gr.; thiosinamin, 5 gr.; water, 1 oz. (2) "Percentage" means one part in a hundred, i.e., 1 oz. in a hundred ounces (by weight) of water. A 10 per cent. solution contains 48 grains in each ounce. (3) We know of no such formula. You can get a kind of green by developing a gelatine P.O.P., but we regard such processes as poor makeshifts. You had far better use carbon than waste time in trying to get out of other papers what they are not intended to give.

BAS RELIEF PHOTOGRAPHS.—I am obliged for the answer to my query re Cameo Photos. You have, however, misunderstood my meaning. I was referring to what used to be known as "Bas Reliefs." But there is, I think, some method of producing these on any style of paper by coating the back of the print with some material, and then pressing it out to the required depth. After which the print is turned over, and the shadows, etc., pressed back again. I understand all these operations can be performed at home with small expense, and save the trouble of having blocks, etc., made.—C. E. C.

There are several methods, and a description of them appeared in the "B. J. Almanac," 1898, pp. 842-850. In Taber's method (patented) the surface of the block to be used for embossing is sensitised, and printed under the negative laid in reverse upon it. The block is then cut out to appropriate depth by hand, and prints, moistened and backed with soft material such as rubber sponge, subjected to pressure on it. Instead of printing on to the block the outlines may be drawn on transparent paper laid on the photograph, and from this transferred with the aid of "carbon" copying paper to the block.

COPYRIGHT.—I should be greatly obliged to you if you would give me your opinion as to whether I have a clear case for prosecution re infringement of copyright. A man asked me to take photographs, so as to supply him with bromide postcards to sell at 2d. each. I went out three miles and took photograph, entirely at my own expense (which I copyrighted), and

supplied him with three dozen postcards, for which he paid me 4s. 6d., clearly understanding that a large number would be wanted later on. Soon after the customer came and found fault with the photograph, said it was not a good one, and that he should not require any more; and a few weeks afterwards I find he had sent it away and had it copied, and selling copies. I have enclosed one of the original ones, on which you will see my name, also one of the copies on which my name is partly erased, and the word copy written on. Will you please give your opinion of the original, and say what your views on the whole matter are?—HE HE.

As you were paid for your work the copyright is not yours, but your customer's, to whom belongs the exclusive right to copy it. You have no case at all. If you thought you were retaining the copyright by charging a reduced price, you should have obtained a written assignment of the copyright and have at once registered it.

PURIFYING OX GALL, ETC.—(1) Can you give me details of any process for preserving and purifying ox gall after it has been extracted from the bladder? The process should not (of course) interfere with or alter any of the properties of the gall. (2) Can you give me a formula for producing a tone on bromide prints the same as that on the print enclosed? The chief characteristics should be quick working and as simple a bath as possible, consistent with getting the desired result. The hypo alum hot bath would do very well, except for certain drawbacks, which prohibit its use for any particular purpose.—ARGENTYPE.

(1) We do not know where our correspondent proposes to carry on his purification, but if he is a married man we should strongly advise him to send his family out for the day, or he may strike trouble, as fresh ox gall does not "reek of Rimmel"; as the purified gall may be obtained from any chemist, we personally should prefer to purchase it. The usual method of purification is as follows:—Take a pint of fresh ox bile and evaporate down to five ounces, mix it with half a pint of spirit, stirring well, allow the mixture to stand twelve hours, and decant the clear solution or filter, wash the filter paper with a little spirit and then evaporate the filtrate down to a suitable consistency, or, of course, it may be kept in the dilute state. (2) The tone can probably be obtained by bleaching the print in

Potassium ferricyanide	280 grains.
Ammonium bromide	360 grains.
Water to	20 ounces.
washing well and then immersing in	
Sodium sulphide, pure	60 grains.
Water	20 ounces.

till the brown colour is obtained. The print should be allowed to remain this solution for some time after the action seems complete, and then well washed.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received *subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.*

EX CATHEDRA.

Photography of the Eye. Dr. Lucien Howe, of Buffalo, in a letter to the "Scientific American," claims priority, in photographing the interior of the eye, over Dr. W. Thorner, whose method was described in our issue of February 3. Dr. Howe's method was communicated to the American Ophthalmological Society in 1887, and since then better results have been obtained by Professor Dummer, of Gratz, by means of a large and complicated apparatus. Two principal difficulties in this problem, says Dr. Howe, are to do away with the reflection from the cornea and to obtain a plate sufficiently sensitive to the red rays reflected from the living retina. He would be glad to co-operate with others who might also be interested in the subject; and if a satisfactory photograph can be obtained by a process so simple as to make it of practical value, it would be creditable to the one who succeeds, and certainly would assist in advancing our knowledge of the interior of the eye and its various diseases.

* * *

Methylated and Pure Alcohol. It has often been said that methylated spirit is frequently drunk by "topers" in the Midlands, and it would seem that it is also consumed largely in the Isle of Man. We read that a Bill has been introduced into the Manx Legislature for regulating the sale of methylated spirit. The measure has been prompted by the necessity of preventing the use of this spirit as a beverage, especially among the lower classes, during Sundays and hours when public-houses are closed. The Bill provides that only licensed persons may sell the spirit, and that publicans are to be prohibited from taking out methylated spirit licences. Also that the

sale of methylated spirit, by anyone, is to be prohibited between Saturday night and Monday morning. Where legislation of this kind becomes necessary, there can be but little doubt that the methylated must be considerably used as a potable spirit, repulsive as it is to most people, particularly with the addition of mineral spirit which is now compulsory. Its intoxicating properties must be great when we consider that the strength of the ordinary methylated spirit of commerce is from sixty to sixty-five over-proof, while the usual spirits as sold at public-houses are from fifteen to thirty per cent. under proof.

* * *

Duty-free Alcohol.

The Commission appointed some time ago with regard to permitting the use of duty free alcohol for manufacturing purposes has not yet issued its report. Up to the present English manufacturers of certain chemical preparations, where methylated spirit will not answer, have been heavily handicapped by the Germans. In Germany pure alcohol, duty free, is allowed to be used for purely manufacturing purposes, and it is to be hoped that a similar state of things will obtain here in the near future. Except for the collodion process, alcohol is not now much used in photography. In the manufacture of the collodion the methylated spirit will not answer, hence duty-paid spirit has to be employed, and this greatly increases its cost. If duty-free alcohol were allowed to be sold it would cost less than methylated spirit, inasmuch as the wood naphtha, of which ten per cent. has to be added, is more costly than the alcohol itself. If refined naphtha could be used for methylating it would probably do no harm in the collodion process, but it is not allowed; only a crude form can be used. All the naphtha used has to be submitted to the Excise authorities, and they will not pass any that is not of a crude kind. The addition of the naphtha to the alcohol has also to be made in the presence of an officer of the Excise. When methylated spirit was first allowed to be sold, they were not so particular, and, at one time, methylated alcohol strengthened up to the commercial absolute—'805—was for a time an article of commerce, but that was altered many years ago. Now it is illegal to redistil the spirit either with the view to strengthen it, or in any way purify it. If the nauseous compound—the present methylated spirit—is so largely used as a potable spirit as it is asserted to be, it is scarcely to be wondered at that the Excise authorities are somewhat chary of allowing any alteration.

* * *

American Copyrights in Britain.

A letter from Mr. John Philip Sousa, the well-known "March King," appeared in the "Times" of Monday last, protesting against the piracies of his musical copyrights in this country. We follow Mr. Sousa in his complaints because the incident raises a point in the law of artistic

copyright, which may frequently be of importance to photographers. The mutual benefits which are extended to British and American citizens are based, not on the Berne Convention—to which the United States is not a subscriber—but on the Chace Act, passed by the United States Government in 1891, whereby the benefits of American copyright are extended to citizens of foreign States who grant to Americans “the benefit of copyright on substantially the same basis as its own citizens.” A number of countries, among which is Great Britain, have been “proclaimed” by the United States Government as sharing in the concession of the Act. Citizens of these countries, on taking out copyright in America, can obtain the protection granted under American law, and, on the other hand, American citizens, as Mr. Sousa points out, are entitled to protection in the proclaimed countries to the extent granted to citizens of those countries. Mr. Sousa complains, in regard to musical copyrights, that the reciprocity is all on one side; but he is probably mistaken, for British composers have suffered worse things at the hands of the music pirates than have foreigners.

* * *

Artistic Copyrights and the Chace Act.

On the passing of the Chace Act in 1891, official assurance was given by the British Government to the United States to the effect that foreigners can obtain British copyright on first publishing the work in any part of the British possessions, and that subsequent publication in a foreign country does not affect their position in this respect. It was further stated that residence in a British possession was not necessary to obtaining British copyright. These conditions may or may not hold good in regard to literary copyright—though it is commonly supposed that they are valid—but as applied to copyright in artistic works, the statements we have just quoted certainly seem incompatible with the Copyright Act of 1862, wherein the benefits of British copyright are extended only to a person who is “a British subject or resident within the dominions of the Crown.” There is thus a doubt as to the validity of the Chace Act in respect to photographs, and even assuming that the discrepancy above cited can be explained, the obtaining of copyright in the States by a non-resident foreigner is hedged about with so many formalities that for practical purposes the game is not worth the candle.

* * *

Alleged Celluloid Dangers.

Reference to this was made in “Ex Cathedra” last week, and if the cases quoted are authentic they would tend to shake confidence in articles made of celluloid generally. As a matter of fact, during the last quarter of a century or so, celluloid or its analogue, “xylonite,” for the two differ only in name, has largely taken the place of ivory. It is used considerably for pianoforte keys, knife-handles, serviette rings, and such-like things in domestic use, but we have never heard of a case of spontaneous combustion in them. Collars and cuffs, combs, brushes, etc., made of celluloid or xylonite have long been in use, but no instance of spontaneous ignition with them has yet been chronicled. Accidents with them have at times happened, but only when they come in contact with a flame or great heat. Celluloid, of course, is highly inflammable when a light is applied to it, or it is subjected to a strong heat, as it sometimes is when incautiously used in the cinematograph, and then accidents may be expected. Xylonite or celluloid dishes are well known in the photographic world, but whoever heard of one of them taking fire spontaneously? As we said in the former note, it is a pity that more details were not supplied by those who wrote

to our German contemporary. It is hoped that these will eventually be forthcoming, but until they are our confidence in celluloid for ordinary purposes will remain as it is. It is noteworthy that the celluloid that is said to have ignited spontaneously was in the form of comb for the hair. But such combs and hair fasteners made of celluloid, in imitation of tortoiseshell, have long been in use in this country by ladies, but we have not heard of a single case of their firing spontaneously.

* * *

Self-ignition of Celluloid.

Meanwhile, the cases of the spontaneous ignition of celluloid are further discussed in our contemporary, the “Chemiker Zeitung,” where Dr. W. Normann takes pains to set at rest any misgivings which may have arisen in the minds of interested parties. The inflammation of the ladies’ hair-combs, he affirms, is capable of explanation in a way which acquits celluloid of dangerous properties except under special circumstances. The hair-comb, it is pointed out, is the invariable culprit when charges of incendiarism are made against celluloid, and Dr. Norman has found that by artificially imitating the conditions under which a comb is exposed to radiant heat, when worn in the ordinary way, the temperature of the enveloped celluloid may be as high as 100 deg. Cent., and this he regards as dangerously near the point at which celluloid commences to decompose. The temperature of the unenclosed thermometer under the same conditions was only 40 deg. Cent., a surprising difference, but the writer obtained identical figures on making a second test. In other words, it is suggested that the enclosure of celluloid in a material such as hair or wool, which is an extremely bad conductor of heat, provides the conditions for combustion of the celluloid on exposure to radiant heat. That certainly seems a legitimate conclusion from the facts, and is satisfactory in so far as it confines the conditions of self-ignition within very narrow limits. At the same time, we cannot conceive that such conditions can obtain except under very exceptional circumstances, nor, in our opinion, would they bring about the combustion of celluloid of proper manufacture.

ANOTHER COPYRIGHT ACTION.

ONCE more the High Courts have been engaged in a suit which is of interest to owners of copyright works, inasmuch as it involves points that we have had at times to express opinions upon through the Answers Column. One of the points in the case was dealt with in an article last week with reference to innocent agents. Another point was one upon which our advice is frequently asked. It is: Certain alterations are made in a copy, or some portions omitted; is it still an infringement of copyright? The action in question was argued in the Chancery Division on the 9th and 10th ult. before Mr. Justice Kekewich, when judgment was reserved. This was delivered at great length on the 21st, the report of it taking up a full column and a half of the “Times.” The action was Hanfstaengl v. W. H. Smith and Sons. Briefly the case was as follows:—In “Munsey’s Magazine,” a work published in America, appeared, in connection with an advertisement competition, a number of small reproductions, amongst which was one of Thumann’s picture, “Nature’s Mirror,” of which the plaintiff holds the copyright. This magazine was imported here, and sold by Messrs. Smith. They were unaware that the magazine contained the copy until their attention was called to the fact by the plaintiffs, and, when it was, this particular print, which was very small—it might be covered by a penny-piece—was taken out. The action was for an injunction and damages, merely

nominal ones being claimed in the first instance. But the parties did not come to terms; hence the action. In the trial it was contended that the reproduction was not an infringement, inasmuch as a portion of the background and the wings of Psyche did not show. Also that the print was so small and crude that it could not interfere with the sale of the plaintiff's reproductions of the original picture. Now the Copyright (Fine Arts) Act makes it illegal to "repeat, copy, colourably imitate, or otherwise multiply for sale, hire, exhibition, or distribution, any such work or the design thereof." "The design thereof" was an important point in the judgment. Mr. Justice Kekewich quoted Lord Justice Davey, in a former case, who said, "But it is said that the Act protects, not only the picture, but the design. These words are probably inserted in order to bring within the protection of the Act a copy in a different medium—for instance, a black and white copy of a painting made by an engraver, photographer, or a draughtsman, but it must still be the design of the picture, and not a mere outline or descriptive sketch of it." Continuing his remarks the Judge said that in dealing with a small surface—as in the case of the print in question—for convenience some portions have been blotted out. The background is gone and the wings, which were a poetical addition to the picture, and are preserved in all the photographs, are missing. Still there is the lady with the same drapery and in the same position, kneeling on the same rock, and intently gazing on what must be water. . . . "By this time I am," he said, "tolerably familiar not with the original picture but with the photogravure which has taken its place for the purpose of this trial, and may be regarded as a fair equivalent. I cannot turn," he added, "from the latter to the magazine

without being reminded of Thumann's picture, and instinctively recognising the work from which the case copy is taken. Coming to the question of damages, the Judge said in effect that this crude reproduction could not in any way injure the artist's reputation, nor could it injure the sale of the larger reproductions of the picture, but with the smallest sizes issued the case might be different by vulgarising the reproduction. He did not think that any serious injury that could be measured by £ s. d. had been done; but he adopted the plaintiff's argument that, if he desired to protect his copyrights, he was bound to take action even in a case which was on the face of it of a trumpety character, or run the risk of encouraging more serious infringements. He added in conclusion: "For the reasons above given I think the plaintiff is entitled to a verdict for nominal damages; and, seeing that he has come here to assert a right, the assertion of which was, as already stated, required for this protection, I see no reason why he should be deprived of his costs, notwithstanding that the defendants acted innocently, and, on having their attention called to the matter, did their best, so far as I know, with complete success, to obviate any further cause of complaint. There will be judgment for the plaintiff with a farthing damages and costs of the action." We have dealt with this case somewhat at length as it fully confirms what we said in an article last week with reference to the liability of innocent agents, and the defendants in this action were quite innocent agents. It also illustrates that if certain portions of a picture are removed, or omitted, it does not evade the Copyright Act. There is still the "design thereof," which is met by the Act. Queries on this point we have frequently had to reply to in the Answers Column.

THE WEEK IN HISTORY.

The Misfortunes of Daguerre.

EXACTLY sixty-six years ago to-day—on March 3, 1839—a fire had broken out in a building near the present Hôtel Samson in Paris. In a couple of hours the whole edifice was practically destroyed. The building was the "Théâtre du Diorama" of Daguerre. For nearly twenty years it had stood on this spot until a careless workman, bringing a lighted taper near a recently varnished painting, set it ablaze and thus ignited the combustible scenery with which the scenerium was stocked. The conflagration brought Daguerre, who was fifty-two at this time, into sore financial straits. Ever since the time when his dioramic effects had startled Paris into a new sensation, the theatre had been one of the show places of the capital. It appears that Daguerre obtained—and spent—a handsome income from his enterprise, and that he spared no pains and money to enhance the realism of the performances. So successful was he that when Charles X. visited the diorama he flung a two-franc piece into the *mise-en-scène* to convince himself that the perspective was actually a painted background.

Apparently Daguerre was the inventor of the system of producing novel effects by means of a canvas painted on both back and front, and illuminated by reflected or transmitted light in varying proportions. The triumphs of this method seem to have been acceptable to the Parisian patron of amusements in the twenties and thirties of the last century, and brought wealth and fame to their originator. These facts excuse, if they do not justify, the mercenary spirit which Daguerre showed when just about this time he completed his invention of photography. His previous source of income had suddenly disappeared; it was not surprising that he should make all he could out of his discovery. Critics of Daguerre have com-

mented severely on his patenting of his process in England immediately after the French Government had granted him an annuity for its publication. But I am not aware that any critic has taken the fact of the dioramic collapse into consideration.

The Diorama as Bonus.

When the settlement with the Government came on, Daguerre appears to have negotiated terms with some adroitness. He was to get so much a year for the rest of his life on account of his photographic process, and he clinched the bargain by throwing in the secret of his diorama. The *projet de loi* in which the Government ratified this agreement dwells on this "graceful concession":—"M. Daguerre has consented to make known the methods by which he produces his diorama, an invention of which he alone knows the secret, and which it would be unfortunate to be allowed to be lost"—reminding one of the cheap-jack who gives away the silver pencil-case with the genuine hall-marked gold albert.

In the textbook which Daguerre published in 1839, he spends a chapter in explaining the principles of his scenerial methods. The very first handbook on photography setting a precedent of "miscellaneity," if I may coin a word! It is a precedent which I fear has been followed more than once in English photographic literature.

Daguerre and Photography in 500 A.D.

There is evidence that in his travels in search of subjects for his diorama Daguerre visited Mount Athos in Turkey, and it has been suggested that he may have obtained a clue to the photographic process which he afterwards published from a manuscript in the Dionysian Convent there. The supposition rests on the rather insecure basis that a manuscript describing a photographic process was stated by Dr. Constantine Simionides, in 1864, to be in the Convent. Mr. Bolas has pointed

out that Simonides did undoubtedly forge certain documents when in straitened circumstances, but that there is not sufficient evidence for doubting his correctness in the case in question. The manuscript which it is suggested Daguerre may have seen was attributed to a monk, Panselennus, living about five hundred years after Christ, and he is said by Simonides to have described a process resembling Daguerreotype.

J. B. Reade and the Invention of Photography.

The inventors of photography trod closely on one another's heels. Talbot, Herschel, Daguerre, and Reade all published their results within the first six months of 1839. The last named was unfortunate in the medium he selected for making known his work, and on that account did not receive a fair share of the credit which was his by right. On the other hand the work of Reade has been distorted, notably by Mr. John Werge, to appear something which Reade himself stated it was not. What Reade actually accomplished—independently of Talbot or Herschel—was the working out of a photographic process in which relatively great sensitiveness was obtained with silver nitrate and tincture of galls, and in which the fixing processes with salt or iodide (as advocated by Talbot) and with hyposulphite (as laid down by Herschel) were employed. March 9, 1839, is the date which can be attached to Reade's process, though he had obtained results at least two years before. But this date appears on a letter written by him to E. W. Brayley, the librarian of the London Institution. This letter was not published until 1847 (the "North British Review," p. 470), and so in the action of Talbot v. Laroche in 1854 it was held that Reade did not make known his process to an extent which could be called publication.

How Reade Overlooked the Latent Image.

Wrote Reade:—"The most important process, and one probably different from any hitherto employed consists in washing

good writing paper with a strong solution of nitrate of silver containing not less than eight grains to every drachm of distilled water. The paper thus prepared is placed in the dark and allowed to dry gradually. When perfectly dry, and just before it is used, I wash it with an infusion of galls prepared according to the Pharmacopœia, and immediately, even while it is wet, throw upon it the image of microscopic objects by means of the solar microscope. It will be unnecessary for me to describe the effect, as I am able to illustrate it by drawings thus produced. I will only add, with respect to the time, that the drawing of the flea was perfected in less than five minutes, and the section of cane and the spiral vessels of the stalk of common rhubarb in about eight or ten minutes. These drawings were fixed by hyposulphite of soda. They may also be fixed by immersing them for a few minutes in salt and water, and then for the same time in a weak solution of hydroiodate of potash (potassium iodide. Eps.). The drawing of the *Trientalis Europea* was fixed by this latter method; it was produced in half a minute, and the difference in the colour of the ground is due to this rapid and more powerful action of the solar rays. This paper may be successfully used in the camera obscura."

From this it will be seen that Reade did not realise the existence of a separate latent image which could be afterwards developed. He was developing his latent image at the time of exposure under the impression that he was in possession of a very rapid print-out process. As he himself admitted in some correspondence published in *THE BRITISH JOURNAL OF PHOTOGRAPHY* for March 1, 1862:—"I was only, as the Judge said, 'very hot.' I did not realise the master fact that the latent image which had been developed was the basis of photographic manipulation. . . . The notion of developing a latent image . . . never crossed my mind."

HISTORICAL.

ORTHOCHROMATIC PHOTOGRAPHY.

I.

[A Paper read before the London and Provincial Photographic Association.]

Where the Ordinary Plate Fails.

In the photographic reproduction of a great number of subjects the ordinary plate produces effects which are accurate and pleasing. Such, for example, are most architectural subjects and black and white drawings. On the other hand, as the only light recorded by the ordinary plate is the blue, violet, and ultra-violet, blue objects usually photograph too light, and green, yellow, and red ones too dark, unless these latter happen to reflect sufficient ultra-violet or violet to be recorded.

I propose this evening to consider the means at our disposal to photograph any subject, whatever its colour, either to give a good rendering of its light and shade, or to accentuate or reduce its contrasts.

Properties of Orthochromatic Plates.

The majority of orthochromatic plates on the market exhibit a type of colour sensitiveness which is conferred by the use of erythrosin in the emulsion. This consists (over and above the normal blue sensitiveness) in a sensitiveness to the yellow-green and green light of the spectrum, and in a somewhat lower sensitiveness to the blue-green. Panchromatic plates are, in general, sensitive to the spectrum yellow and orange-red in addition to the green, but the green sensitiveness remains much greater than the red in nearly all cases.

Great improvements have been made in colour sensitisers during the last year or so; among the most notable introductions being Pinachrome, Pinaverdol, and Homocol. In most cases the sensitiveness is not even, but exhibits more or less well-marked maximum effects to certain wave-lengths.

Some slight indication of the relative sensitiveness of plates to blue, green, and red is afforded by the exposures given in three-colour work, where one finds such ratios as 1:8:12, 1:2:16, 1:6:16, and 1:4:32; and as in most of these cases the action of the blue light is considerably subdued, it will be seen that the added colour sensitiveness is much less than the normal blue sensitiveness.

By introducing into the emulsion certain yellow dyes which act as filters, the blue sensitiveness of some commercial plates is subdued relatively to the green without any loss of speed. In collodion emulsion work the above order of things is to some extent reversed, the green or red sensitiveness being predominant with many sensitisers.

Types of Orthochromatic Light-filters and their Uses.

All the filters detailed here consist of solution of aniline dyes, etc., and they are specified, according to the number of milligrams of dye contained in each cubic centimetre (parts per 1,000) of solution, the solution being held in a glass cell having an internal separation.

1 cm. Filters made from flashed or pot-metal glass are in fairly common use, but they are unreliable in their action. Frequently, although orange in hue and greatly increasing the exposure, they effect but little colour correction, because of the violet and ultra-violet rays which they transmit. Ultra-violet should not be transmitted by an orthochromatic filter if it can be avoided. There is practically only one way of ascertaining exactly how any particular filter and plate are acting, and that is by means of the photo-spectroscope—a test which may sometimes be supplemented by the colour sensitometer.

TYPE I.—Yellow filter subduing the blue and violet.—This is a fairly good class of filter for general work. It reduces the photographic effect of blues and whites and allows the yellows and greens to be recorded on an erythrosin type of plate. Unfortunately a filter of this type depends very largely for the correctness of its effect upon the relative sensitiveness of the plate used to green and blue, and as plates vary very much in this respect it really requires adjusting to almost every plate. A solution of brilliant yellow employed in a strength of 0.04 mgm. per c.c. gives a very good result with many green sensitive plates. The effect of this filter in landscape work is to increase slightly the detail in the greens, and also to bring out the clouds somewhat.

TYPE II.—One of the most useful filters for general work is one absorbing the whole of the ultra-violet, violet, and blue up to about λ 4,800. It might appear at first sight that such a filter would not give any good results since it entirely absorbs certain light visible to the eye, but owing to the fact that these colours rarely occur by themselves in Nature, never in landscape work, bad effects from this cause are not often seen. It will record blue colours quite well because of the blue-green and green that they reflect; yellows and greens are also well rendered. Violet and crimson colours are liable to be too dark, however, while the same remark applies to reds and deep oranges.

Such a filter has two very important advantages. Firstly, it can be made with dyes that are very transparent to the green and blue-green, and, secondly, as nearly the whole of the light to which a plate is normally sensitive is absorbed, and but little, except the sensitiveness conferred by orthochromatising, utilised, it is much less liable than the first type to give variable results with different brands of plates. Suitable compositions for this type are:—(1) Tartrazin 0.2 mgms. per c.c., or (2) Naphthol yellow S, 0.5 mgms. per c.c. The first dye is the more convenient on account of its great solubility.

The action of this filter in landscape work is to enhance relatively the photographic effect of the green foliage, and retard that of the blue sky, so that the clouds can often be well rendered in a negative at the same time as the green trees and fields, while the rendering of detail at a distance appears to be assisted. I do not, therefore, recommend this type of filter to those who desire to obtain the so-called "artistic" and "atmospheric" effects. There is a defect, which I believe might arise if too much blue-green were absorbed by the filter, and that is an apparent over-correction whereby trees are made to appear snow white. I am, however, inclined to think from such negatives of this kind that I have seen, that they were taken in very brilliant sunshine, and that they may be good renderings of the scenes as they appeared.

TYPE III.—True Orthochromatic Filter.—Perhaps the ideal combination of filter and plate is one which renders all objects according to their luminosity, irrespective of their colour. This is the type of filter of which a great deal is talked about in conjunction with the correct rendering of colour values, but they do not seem to be often produced or much used. As a matter of fact, their construction presents some little difficulty, and one does not often find the need of them. The first requirement is a plate sensitive to practically all visible light; the only kind which perhaps may be neg-

lected is the extreme violet. Now as there is no dry plate on the market sensitive to the whole of the red, one must start with the best panchromatic plate available. If the plate is sufficiently sensitive to red, which it rarely is, a filter of type II. might suffice. Generally orange-yellow dyes, such as Brilliant Yellow, which have a gradual absorption, greatest in the violet, and least in the red, are the most useful. A filter containing 0.08 mgms. of Brilliant Yellow per c.c. works well with a Lumière C. plate.

The colour sensitometer test is an excellent one for this type of filter, but the exact spectrum composition of the colours used must be known or no information can be obtained which will be useful in the adjustment of the filter. Reds, and sometimes greens and yellows, are liable to transmit sufficient violet or ultra-violet to produce a considerable effect on a photographic plate, without it being noticed by the eye. Suitable dyes for a colour sensitometer are Fast Red together with a little Tartrazin, strong Tartrazin, Naphthol Green, and Victoria Blue. These have to be adjusted, conveniently by photographic film, to a uniform visual luminosity, and a photograph of them should render all the patches equally bright.

TYPE IV.—Orange Filter.—A filter transmitting the red and part of the green used with a panchromatic plate is often very useful, particularly in photographing oil paintings with reds, oranges, and yellows. An interesting point with this filter is that although it does not transmit any pure blue or blue-green light, yet pigment colours of these hues generally reflect sufficient green and red to give a fairly correct rendering. Brilliant Yellow 1 mgm. per c.c. answers very well for the filter.

TYPE V.—Red Filter.—A filter similar to the red one used for tri-colour work is sometimes useful for lightening the reds of a dark picture.

The following is the composition of such a filter:—

Rose Bengal	0.5 mgm. per c.c.
Tartrazin	1.5 mgm. per c.c.

Dry and Liquid Filters.

These both have their respective advantages. For the purposes of experimental work, and perhaps also for work in the photographic studio, it is convenient to use liquid filters, the coloured solution being contained in a glass cell having flat sides. Only one cell is really necessary, and the solutions are poured in when required. Care must be exercised that the solutions do not fade or decompose. The yellow and red dyes recommended here are fairly stable.

However, filters in a dry state are more convenient if photographs have to be made away from the studio. In making dry filters corresponding to liquid ones, they should be re-tested, since the dyes do not always absorb in exactly the same manner when dry as they do in solution.

Regarding the glass used for dry filters, it should be homogeneous, and should have flat surfaces, but it does not matter if they are not strictly parallel.

The usual methods of making dry filters are to support the glass on a levelling table and coat with hot gelatine solution (8 to 10 per cent.), and when set to stain to the required depth in a solution of the dye, and then let it dry in a place free from dust; or to coat the glass with collodion, wash the ether and alcohol out, and then dye the film; or if the dye is soluble in alcohol, it can be dissolved in the collodion. In either case a cover glass must be cemented on with Canada balsam. A more exact method is to dissolve a measured quantity of the dye in the gelatine solution before coating.

A. J. BULL.

[The second part of this paper will appear next week. Eds., B.J.P.]

SOME PROBLEMS IN SHUTTER DESIGN.

II.

Control of Time of Exposure.

One of the chief problems in shutter design is the exact measurement of the intervals of the time during which the shutter remains fully open. The escape of air from the chamber, first applied to

Fig. 4.

shutters by Newman and Adams, is the means most commonly employed for this purpose. But its general failure to control such short intervals as two or four hundredths of a second led me to inquire closely into the value of friction for this purpose.

Fig. 5.

The Failure of Control by Friction.

The theory of the engineering schools is that friction is independent of velocity, but if this were true, friction could not be used to control velocity as we know it does in shutters which contain friction brakes. I therefore endeavoured to discover, by means of the apparatus roughly sketched in Fig. 4, to what extent and through what range friction varied with velocity. Fig. 5 shows some of the results. These curves which give the relation of friction in ounces to the corresponding velocity of the falling weight in seconds per foot, show that below a certain critical point velocity does not much

depend upon friction, while above this point the contrary is the case, and a variation of friction of only 8 per cent. makes as much as 80 per cent. change of velocity. It is obvious that for controlling velocity usefully, neither of these extreme conditions would serve and I therefore endeavoured to discover materials and conditions of pressure, etc., which would yield results approximating in graphical expression to a straight inclined line. Fig. 6 is the best effect obtained, and this is not unpromising. But all these experiments showed that friction varied widely at different times, being increased sometimes in the ratio of one to twenty merely by letting the apparatus rest for a day, and reduced correspondingly by active employment. This consideration appeared to wholly discredit friction as a means of accurately controlling shutter motions; the idea was accordingly abandoned, and attention was given to improving the use of pneumatic action.

Pneumatic Control.

The original pneumatic regulator for shutters consisted of a cylinder fitted with a piston, packed to prevent leakage, whose motion was retarded more or less by varying an aperture provided for the escape of the imprisoned air.

Fig. 6.

In the modern shutter the pneumatic regulator is called upon, not to vary a rate of motion, but to measure intervals of time. Accordingly it has been found that the packing of the piston and the variable air exit may both be dispensed with, the piston is fitted loosely within the cylinder, the air escaping between them acts as a lubricant and intervals of time are varied, not by varying the rate of the piston's motion, but by varying the distance through which it moves.

Now, in the ordinary shutter, which is intended to control times varying between one second and one-hundredth of a second, if the distance through which the piston moves when measuring one second be, say, half-an-inch (and it is limited by the need for compactness) then the distance through which it moves when measuring one-hundredth of an inch is only five-thousandths of an inch and the trouble is this: that with an elastic substance like air, which has to be compressed in volume before leakage will occur, that small interval of one-hundredth of a second, and even longer intervals, are generally occupied in compressing the air and by the effects of impact and inertia, and there is no time for the leakage, upon which we depend for time measurement, to come into play. This is why in the ordinary shutter, as is well-known, the three or four shortest exposures are practically the same, and not as marked on the dial. The remedies for this defect must be sought in increasing the rigidity of the air cushion, and in reducing the inertia, and controlling the impact of the moving parts.

Compression v. Extension in Pneumatic Control.

It does not seem to have been recognised how much more rigid air is in compression than in extension. This is shown in Fig. 7, which

Fig. 7.

represents in outline a cylinder containing a loosely fitting piston at rest, with an air space D, between the piston and cylinder ends. In this position the air within is at the same pressure as that without, and the resistance to motion of the piston is zero. Let us call D $\frac{1}{2}$ in. If now we suddenly move the piston through $\frac{1}{2}$ in. so that the air volume is reduced to half, the difference between the inside and outside air pressures will be about 14.7 lb. to the square inch. This is the resistance now offered to further motion of the piston. If, however, instead of compressing the air we extend it as is frequently done in shutter regulators, we shall have to move the piston, not $\frac{1}{2}$ in. only, but an infinite distance in order to get the same resistance of 14.7 lb. This very striking statement is a caricature only because such high pressures are never reached in shutter regulators. But the principle it displays remains true: we must use the air in compression rather than in extension.

Actuating the Piston.

The next point of importance in securing accurate measures of short

time intervals is to control the effect of impact on, and the inertia of, the moving piston.

In being moved to measure a very short time interval, it is inevitable that the piston be moved quickly. But if it be suddenly struck by the part which actuates it, the energy which the piston thus receives may carry it at once beyond the point required, and the effect of air leakage on the timing of the shutter will be lost.

It is the usual practice in shutters to strike the piston in this way, in order that the pneumatic device shall act also as an air cushion to stop the opening shutter without shock. This use as a buffer is however, quite inconsistent with the true purpose of the pneumatic regulator, and to abandon it leads to very much greater accuracy, in the control of short time intervals.

Springs in Compression.

The energy used to operate shutters is generally stored in springs which are set by hand, and for some obscure reason the springs used

COMPARATIVE DIAGRAMS OF TENSION & COMPRESSION SPRINGS
EQUAL STRENGTH IN WORKING RANGE WITHIN 10%

Fig. 8.

in shutters are generally helical springs used in extension, although compression springs having the same strength and range of action are, as shown in Fig. 8 much more compact.

WILLIAM TAYLOR.

[In consequence of great pressure on our space this week the conclusion of Mr. Taylor's paper is held over until the next issue. —Eds. B.J.P.]

PLATINOTYPE PRINTING.

A PAPER on platinotype printing by an expert such as Mr. W. H. Smith, of the Platinotype Company, is likely to not only draw a record attendance to any photographic society's meeting, but is likely to impart more practical information to those present, regarding this popular process, than any amount of demonstration by the dilettante user of the paper. Such proved to be the case at the meeting of the Croydon Camera Club, on Wednesday last, and Mr. Smith's remarks were further emphasised by the fact that nearly 200 platinotype prints were produced, and later, distributed by lot amongst those present.

Black Image Papers

The lecturer, dealing first with the black image papers, said it was important to allow full development, which with the bath at 60 Fah., would take place within 30 seconds; with correct exposure over-development was impossible. If prints had been accidentally over-exposed, development had to be arrested at an earlier stage by plunging them in the acid bath directly the right depth was attained, but the results obtained were not so good as in the case of normal exposure and development, and there was a tendency to granularity. Harsh negatives might be dealt with by under-printing, and developing at 140 Fah. In this connection old paper gave softer prints than new, a fact which might be taken advantage of. For very flat negatives, or when using stale paper, the addition of one

grain (in no case to exceed two grains) of bichromate of potash to every 20 oz. of developer, gave noticeably increased contrasts. This property gradually wore off in the developer, and might be compensated by the very cautious addition of fresh bichromate. Unless any special object was in view, such as local treatment, or sketchy vignetting, he did not recommend the use of glycerine; it gave a somewhat warmer black, less contrast, and a slight loss of quality.

Intermediate Tints.

Mr. Smith then proceeded to show how intermediate tints, between cold black and warm sepia, might be obtained, which may be tabulated as follows:—

Paper.	Developer.	Temperature.	Colour.
Cold bath	D Salts	60	Cold black
"	"	140	Warm "
"	Old Sepia	170	Brown "
Sepia	Sepia	60	Cold Sepia
"	"	170	Warm "

Sepia Tones.

The "Sepia" process was next considered, and Mr. Smith explained that the paper itself, and not the bath, possessed the "toning" quali-

ties; an old bath, however, gave richer tints than a brand new one, owing to what it had derived from the paper. To obtain the best colour the temperature of the bath should not be allowed to drop below 160, or rise above 180 Fah., which might damage the paper; 170 Fah. might be considered normal. Development was complete within a few seconds. Immersion in the acid baths should not be too prolonged, provided a fair quantity of solution was used. 5 minutes in the first, and 10 minutes each in the second and third was sufficient.

After Treatment.

Platinotype papers did not require a long after washing; three or

four changes for 10 or 15 minutes was ample, after which the prints might be suspended, which was preferable to drying between blotters. Owing to a hot developer being used, the necessary exposure to light was about 25 per cent. less than would be given in the cold bath process, and it followed from this that heating the developer was within limits, a remedy for under-exposure, with the latter.

Printing might be accurately gauged by an actinometer; the lecturer preferred "Johnson's single tint" for this purpose. He did not advocate mercury toning of black papers; in nearly all cases a distinct difference in colour between the high lights and shadows was observable.

TIME DEVELOPMENT.

II.

[The following is the second portion of the paper by R. Child Bayley recently delivered before the Society of Arts. The preceding portion, published last week in the *BRITISH JOURNAL OF PHOTOGRAPHY*, dealt with the principles of the system. The mechanical aids to carrying it out are now considered. We regret that we have not space for the discussion, in which the Chairman (Mr. George Davison), Mr. Chapman Jones, Mr. J. Sterry, Mr. W. Thomas, and others took part.—EDS. B.J.P.]

Modern Mechanical Methods of Time Development.

I now reach the second portion of my paper, which deals with appliances for time development. Before referring to them more specifically, it would be well to point out that there are two distinct systems by which time development can be accomplished. In one, we note the time taken for a certain part of the image to make its appearance, multiply that time by a factor which depends upon the developer used and the development factor at which we aim, and take the result as giving the time of complete development. This is the Watkins system, and as it has already been brought before this society by the gentleman best qualified to deal with it, I need not to-night go over the ground already covered by Mr. Watkins, but will merely refer to the "*Journal of the Society of Arts*" for December 5, 1902 (vol. li., p. 42), in which his paper will be found.

The Case of Over-Exposures.

Before leaving Mr. Watkins's system I would like to make one more reference to it. It has been urged against his method of development that it results in under-development of cases of over-exposure, and if his rules for development are rigidly carried out, without exception, there is no doubt that this is the case.

It has been foreseen by him, however, for in a passage in his book which describes his method, speaking of over-exposure, he says (p. 81): "It is, perhaps, even a better plan to develop half as long again, and afterwards reduce with the ferricyanide reducer, which reduces the lower tones more than the upper." It must never be forgotten in considering the Watkins method that it is one which deals both with exposure and development, and that those who master his system and bring merely an average degree of intelligence to bear upon its application to their own practice, will not know much about over or under exposure except what they read.

In the other system, a definite developer at definite temperature is allowed to act upon the film for a definite time, no inspection of the image being necessary, nor, indeed, with some forms of apparatus, possible. This is the method adopted in the "*Tyma*" and in the "*Kodak*" developing machines, examples of both of which are before you.

Ocular Control of Machine Development.

The "*Tyma*" machine, which is the invention of Mr. Max Reichert, was patented in 1901 (No. 14,079), and was the first time development machine to make its appearance on the British market; having

originated, so its inventor informed me, from an editorial article of my own, written and published in "*Photography*" in the previous year. It is a curious fact that, so far as my examination both of British and American patents has gone, the "*Tyma*" is the one and only mechanical apparatus for time development for which protection has been granted, if we except the various forms of automatic photographic machines in which the principle had necessarily to be employed, but in which the development was only one incident in a series of automatic operations. Even the best known, and certainly the most ingenious of machines, the "*Kodak*," as we shall see later, was protected, not as a machine for time development, but with the necessary window and peep-hole for examining the progress of the operations. For a good many years there have been quite a number of patents granted for enclosed dishes or stands in which development can be carried out, but they all provide for the necessity of watching development. In fact, they are simply little dark rooms, outside of which the user remains and watches through a ruby glass what goes on. Yet the patentee of the "*Tyma*" in his specification talks of "the well-known principle of time development." The "*Tyma*," however, has fallen from grace, and in the latest pattern, which is on exhibition, it will be seen that it is provided with a sliding shutter which covers a ruby window, although this cannot be of much service, as the opening is along the edges of the film.

The "*Tyma*" Apparatus.

The two diagrams now shown (Figs. 2 and 3) are taken from Reichert's specification, and will serve to make the working clear. One or two minor alterations have been made in its general design for manufacturing purposes, but it is still essentially what is now seen in these diagrams. It consists of a metal or other box, with a light-tight lid. In the box and lid are three openings, D and C, circular

Fig. 2.

tubes for the passage of the solutions, and M a flat tube practically the width of the box. The way in which the film was immersed was a very ingenious one, and in my own practice—and I used the "*Tyma*" for some little while with perfect satisfaction—never failed. The spool of film with its black paper was placed on trunnions provided for the purpose at G. The black paper was unwound as

little, H being a spring to prevent the spool from unwinding too readily, and was led along under the finger or guide U and pushed up through the flat tube M until it came out of the top; N is a little flap which is raised while the black paper is first put through, and is pressed down again so as to serve as a light trap as soon as there is enough at L to catch hold of; P is a little clip, in which the extreme

Fig. 3.

end of the sensitive film is gripped. All these operations are performed in daylight, and very easily, as the various parts referred to are all attached to the lid, which can be removed and turned upside down for the purpose. Then as much water as can be poured in without causing the syphon to operate is put into the body of the apparatus, and the lid is put on. We then have the state of things shown in Fig. 1, except that the flap at N is closed. On pulling the end of the black paper L the spool unwinds, the black paper comes out of the box, and the sensitive film, film side uppermost, forms a series of loops below the surface of the water. When the end of the film is reached—being attached to the black paper, it enters the tube M, where, by a contrivance for the purpose, the extra thickness of film and paper jams—the photographer knows that his spool is all unwound, and the film is held for the subsequent operations. These consist of syphoning out the water, pouring in a definite developer for a stated time, gently rocking the tank meanwhile, syphoning off the developer at the end of that time, and washing and fixing the film in a similar manner, when the lid can be taken off and the film removed for the final washing and drying.

The same inventor has made a machine for plates, but this need not concern us, as no mechanical methods yet devised for them enable us to do away with the dark room, or, indeed, present any noteworthy advantages over an ordinary dish provided with a light-tight cover, which is what I use myself for such work.

Fig. 4.

We now come to an instrument which is, I expect, well known to every user of films—McCurdy's patent apparatus—which has evolved into its latest form, very different from the original one, the "Kodak" developing machine.

The "Kodak" Machine.

A further diagram (Fig. 4) shows the external appearance of the "Kodak" developing machine in the form in which it was protected by McCurdy (Patent No. 21,243, 1899). You will observe that while it is a very different affair from the machine as it now comes on the market, there is more than a suggestion of it, both in

Fig. 5.

general shape, in the two spindles with external handles, and in the chain which subsequently developed into the well-known celluloid apron. The internal structure is shown in the next slide (Fig. 5). The stages in its development which intervened between the granting of McCurdy's patent and the machine as we know it must be imagined. By the courtesy of the Kodak Company I am able to show you one of the earlier experimental forms, in which we see the machine practically ready for that manufacture on a large scale which has since resulted.

The next diagram (Fig. 6) is copied from the book of instructions, and shows the machine as at present made, with part of the front removed to allow the interior to be seen. The apron, F, is made of ruby-tinted celluloid, of the same material, in fact, as the "Kodak" film itself, but with a red colouring matter added. Along each edge of the apron are corrugated rubber bands, which keep each coil of

Fig. 6.

the helix distinct and allow the fluid to circulate between them. The apron being rolled on the left-hand spindle, the roll of the film is put into the position shown, the black paper is inserted into the slot on the spindle, G, and is wound round it until just before the film itself begins to come off the reel. The end of the apron is then hooked on to the spindle, G, half a turn is given to the handle to secure it, the developer is poured into the right-hand receptacle, the lid is put on, and the handle slightly turned. It goes stiffer and stiffer, until at last the whole of the apron is on the one spindle.

when turning again becomes easy. Inside the right-hand half of the machine we then have what is to all intents and purposes a very long, shallow dish, the bottom of which is formed by the apron, and the sides by the corrugated rubber strips and the sides of the machine itself. This dish is coiled in a helix. On the bottom of it is the black paper, and on that lies the film, face outwards, of course, which is exposed to the action of the developer.

Circulation of the Developer.

We are told to turn the handle slowly, about fifty turns a minute, until the development is complete. At the first glance we might suppose that by so doing the film is carried through the developer, much in the same way as it might be in the old style of developing long lengths of films by see-sawing it through a small dish; but it is not so. There seems to be no doubt that the developer is carried round with the film except for a slight lag. That this is so is confirmed by an experiment which shows that the development factor for exposures developed close up to the spindle G is not appreciably different from that of exposures developed right at the periphery; although, of course, were the liquid stationary and the film dragged through it, we should expect the latter to be higher, since rapid motion of the developer on the surface of a film or plate, such as can be got by violent rocking, always tends to give a higher development factor.

Of late years my experience has been gained entirely with a machine of this type, known as the pattern E, and taking any width of spool up to five inches. I have never had any failure with it which I could attribute to the machine, and although I have developed some hundreds of exposures in it, it is, so far as my observation goes, as good as when I had it; nor has it required any adjustment.

Trade Development.

The next diagram (Fig. 7) shows a combination of four machines with a water motor, such as is supplied for trade purposes. It is used extensively, both by Kodak Ltd., and others for regular trade development, and is not only found to give as high a percentage of

Fig. 7.

good negatives as the old plan did, but gives besides complete immunity from light fog, finger marks, and so on, and a very great economy by the substitution of ordinary for skilled labour. Rumours

of further improvements of the machine are in the air; but nothing definite has yet been announced.

Developers.

The makers of the Tyma and of the Kodak developing machines both supply developers suitable for use with them. Those who use the Kodak packet developers which are pyro soda, have the advantage of knowing definitely the composition of the solution they are using, and of a "time-table" which is given in the instructions, and gets over the temperature difficulty very simply. The developer recommended is made up so that each ounce contains approximately:

Pyro	1½ grains.
Anhydrous sodium sulphite	10 grains.
Anhydrous sodium carbonate	7 grains.

Temperature.

The time-table recommends developing for eight minutes at 45 deg. Fahr., five minutes at 60 deg. to 65 deg. Fahr., four minutes at 70 deg. Fahr., development not being advisable above 70 deg. Fahr. In actual practice I find it simplest to bring the developer to 65 deg. Fahr. by pouring it into a jug that has been warmed with hot water, if need be. It has been urged against this system that the temperature of the developer when development is finished may be very different from that which was ascertained with the thermometer before commencing. It may; but the objection hardly applies to ordinary usage. To get definite figures on the subject I took the temperature of the room and of the developer before and after use during the cold weather recently. The room was 55 deg. The developer was put into the machine at 65 deg., and after development was still between 63 deg. and 64 deg. That was in a cold room. My developing is generally done in a room at 60 deg. to 65 deg., when, of course, the difference would be less or would disappear altogether.

Other Formulae.

There is no need to use the formula given by the makers, of course, provided we find out how long development must be with the selected developer in order to give us the development factor desired. This can be got near enough for most people by developing a few cut films in a dish and noting the time taken for the exposures which seem to be about right to reach correct printing density, noting also the temperature. That temperature and that time will then be approximately what is required. Such a developer is the following, which I have found very suitable for Kodak films. It gives an image that is a little blacker than the pyro-soda formula:—

Pyrocatechin (Katchin)	2 grains.
Crystallised sodium carbonate	24 grains.
Crystallised sodium sulphite	24 grains.

The time of development with this formula, using Kodak film, and a temperature of 65 deg. Fahr., is seven minutes.

When development with this machine is complete, the lid can be slid back, the developer poured off and replaced by water, this replaced by fixing solution, and so on in a way I need not describe. The whole of the operations can be performed in full daylight, without the slightest fear of fogging the film.

I have used some of the other films on the market in the machine, and have found no difficulty in doing so, except that a gummed label or something of the kind must be employed to attach the outer end of the film to its black paper. In the case of the Wellington non-curling film, which in other respects has given me excellent negatives in this way, I have had trouble with the black paper sticking to the gelatine-coated back of the roll film; but I understand from the makers that this is having their attention.

There is one other little piece of apparatus which I have found very serviceable in connection with the developing machine, and that is Stanley's dark room clock.

It is convenient for many other photographic purposes, and is as handy a tool as I have in my dark room.

The Future of Time Development.

There is sound wisdom in the advice "never prophesy unless you know," and I propose to be guided by it now, and I will refrain from asking you to contemplate a vision of photography in twenty years' time, when all developing is done by a mechanical and not by a human "crank." I will ask you to remember, however, how great a change has come over the procedure of the photographer since 1890. It is not a change of apparatus or material so much as a change of method. One by one we are abandoning the old system, according to which we relied upon development to correct errors in exposure, and upon the eye to tell us when development was complete.

The motto for the future seems to be, "Take care of the exposure and development will take care of itself."

Hurter and Driffield, Watkins, Wynne, and others have made the problem of correct exposure far simpler than it used to be; plate and film makers are marking plates with far more definite information than the old "thirty times" or "fifty times"; and the plates themselves, thanks to improved instruments for studying emulsion-making and the changes which take place during the growth of sensitiveness, are far more in accord with practical requirements. The sale of fast plates at a higher price than slow ones, such fast plates being only the slower emulsion unintentionally fogged, is inconceivable now; yet we are assured that not more than fifteen years ago it was the case. There are still some, it would seem, who are inclined to dispute the power of a developing machine to deal with under or over exposure, but, with the advance in means of ascertaining what is the correct exposure, this objection, were it to have a foundation in fact—and I have endeavoured to show that it has not—would have to disappear.

In Three-Colour and Studio Work.

Time development in its broadest sense is unassailable. The moment truth of gradation becomes all-important, time development becomes a necessity; it can only be dispensed with so long as we have no means of testing the results. Skilled three-colour workers tell us that it is impossible to determine the duration of correct development with the eye. They must work by time development, quite apart from the fact that their plates are red sensitive. For studio work, where conditions are fairly uniform, something very much like time development is employed almost unconsciously. The operator who had to treat his negatives with tentative and all the other forms of development which figured so largely in the text-books of twenty years ago might not find his methods traversed, but would certainly hear from his employers on the subject of his output.

For press work, the developing machine has already come extensively into use; it is employed, as the advertisements of its makers remind us, at the seat of war, at the Panama Canal, and elsewhere, under circumstances that would render the old-fashioned style of development impossible.

For pictorial photography its convenience would commend it, if the truth of its results should not. One of the most gifted of photographic picture makers has said that a photographer using his camera as a means of artistic expression should no more have to think of his apparatus than a writer has to think of his pen. That degree of simplicity, I fear, is not attainable; but it can be approached, and a very distinct step is taken when we recognise that, as far as the personal factor is concerned, our negative is completed when the exposure has been made; and it is on the recognition of that fact that time development is based.

THE North Middlesex Photographic Society's annual dinner will be held this year on March 25 in the Caledonian Salon of the Holborn Restaurant.

Photo-Mechanical Notes.

Two Collotype Troubles.

ONE of the most frequent troubles in collotype plate making is the appearance of "wave marks," circular parallel markings generally on the margin of the plate, showing when it is dry. These, unless very large plates are prepared, generally render the plate quite useless. All the most prominent collotype workers, both here and on the Continent, seem entirely agreed, that these markings are due either to vibration or draughts reaching the plate while it is drying, the principal cause being draughts coming through cracks in the drying-box. The drying-box is usually made of wood; but if it is a respectable size it is difficult to get wood of a sufficient depth in one piece. On the other hand, if the sides of the box are made up of more than one piece, then draughts are practically certain to enter. Several remedies have been proposed. One establishment has a double lining, the inner wood sides being separated from the outer by a space of about 3 in., which is lightly packed with peat. This prevents draught, and has the advantage of well retaining the heat. Another good non-conductor and entirely effective draught preventer is plaster of Paris. If the sides of the box are first covered with strained canvas or sacking, then the plaster may be put on to about the depth of $\frac{1}{2}$ in., or some of the fibrous boards which builders now use for ceilings may be cut to size and screwed to the inside of the cupboard, and then plastered over to make smooth and fill up all cracks.

Another trouble that occasionally besets the collotype worker is the tendency of his plate to lift up, or come away from the glass during the printing. If as a rule, the plates work satisfactorily with the same formulæ, then this annoyance can safely be put down to unclean glass. Unless the glass has been thoroughly well cleaned and a good strong acid bath used, lifting is very likely to ensue, the presence of the slightest trace of grease being inimical to success.

Preserving Scum on Half-tone Plates.

Questions and answers on half-tone topics are one commendable feature in "Process Work" (Penrose and Co.), the current issue of which allots two pages to its readers for this purpose. To the querist who states the case of a half-tone which was devoid of colour to start with, and asks for means of preserving the thin and even edge of scum round the work, E. A. Foden writes as follows:—"When getting a half-tone print, clean it thoroughly by letting a little weak chromic acid and water flow over it. Then make up the following solution in a bottle: Nitrate of mercury, 1 oz.; water, 2 to 3 oz.; nitric acid, 1 drop. Give it a good shake and apply with cotton wool to the plate till the exposed upper portions become mercurised. Your print will then look as if printed on silver. Next get the line-etcher's glazed (finishing) roller and put sufficient of best proving ink on as if for pulling a proof; then roll the plate up (dry, of course) from each corner in turn with just a little pressure; this will ink up the enamel and scum together; dust in with bitumen, brush off clean and burn in plate over spirit flame till the mercury deposits disappear and the copper regains its natural colour. The plate is now ready for the first bath, which should be a little less than under normal conditions. Wash off and pull proof, and you will find that you have plenty of body to work upon. If when rolling up plate four ways you find the mercury black up, it is owing to the plate being insufficiently mercurised. Wash the ink off in the usual way and rub on more mercury. The mercury solution given will do for a good number of plates."

Testing Printing Inks.

The usual method of testing inks is merely to expose them to light, but it is equally as important to know whether they will stand the action of acids, alkalies, and sulphurous fumes, and the follow-

ing solutions are suggested in the "Photographische Chronik":—Ten per cent. solutions of hydrochloric and oxalic acids, and a twenty-five per cent. solution of washing soda will enable the ink to be tested for strong mineral acid, weak organic acids, and alkalies and soaps. A mixture of one part of ammonia and two parts of water will show the action of caustic alkalies. Equal quantities of alcohol and water are used for testing the action of spirit; solution of sulphuretted hydrogen and equal quantities of ammonium sulphide solution and water, show the action of sulphurous fumes in the air. The method of testing suggested is to print a flat tint with the ink and cut into eight strips; one being placed in each of the above solutions, the eighth being left for comparison. The strips should be allowed to remain in the solutions for fifteen minutes, then washed in three or four changes of water and dried, and then compared with the control strip. An interesting description is given of the German green postcard stamp, which is a mixture of millori blue and chrome yellow; quite stable to light, but which is turned blue by the action of acids, and yellow by alkalies, and if treated by both it is entirely bleached.

Exhibitions.

BIRMINGHAM PHOTOGRAPHIC SOCIETY'S EXHIBITION.

ON Saturday, February 25, the twentieth annual exhibition of the Birmingham Photographic Society was opened by the Lord Mayor in the rooms of the Royal Society of Artists, who again lent their fine suite of galleries for the purpose.

The hon. secretary, Mr. Lewis Lloyd, must be again congratulated on having got together so much good work. The first impression, perhaps, will be that the exhibition is not so good as we have seen before, but a careful examination soon convinces us that it is of more interest than ever, and although the really fine loan collection which was shown on the first occasion, when these galleries were placed at the disposal of the society, will be missed, yet the general average will be found to be higher than ever. For there is scarcely a single photograph in the whole exhibition that is not good, except several that are wilfully bad, sent in by members who ought to know better.

The judges in the pictorial section, Messrs. F. H. Evans, J. C. S. Mummery, F.R.P.S., and W. J. Wainwright, A.R.W.S., have not awarded so many medals as usual. The lady photographers again show very strong work. Mrs. G. A. Barton has twenty-three frames and receives two silver medals, which entitle her to hold the silver cup of the society for a year. Mrs. Barton's work is very much on the same lines as in former years. Her strongest and best is 104, "A Pair of Spectacles," a vigorous portrait of an old lady, a really fine piece of work, but one feels that the shadows on the face are a trifle too black. This portrait receives one of the silver medals, the second being awarded to 319 C, "Little Round Hat," a portrait in red chalk of the little girl we have seen so often. "Hollyhocks" (319) is not a success; the flowers are too dark, and a smudge in the outline of the lady's nose is unpleasant. "Portrait of Mrs. W. J. Seal" (42), a full-length of a lady in a white dress, against a dark door, is, on the whole, the most satisfactory photograph Mrs. Barton has ever exhibited. Nevertheless one cannot help feeling that this clever lady exhibits too many, and that if, instead of sending twenty-four frames, the same time and care had been expended on six, the results would have repaid the sacrifice, and sacrifice is one of the great guiding rules of Art.

Mrs. G. Arbuthnot has several portraits in a dainty, delicate style which she has made her own. "A Portrait" (82) reminds us

of a delicate sketch in pencil; while the "Bishop of Birmingham" (22) shows that Mrs. Arbuthnot can produce strong, vigorous work. Mrs. Wooton, in addition to "A Bit of Venice" (10), an excellent photograph of a canal in that lovely city, shows some good portraits of children. Mrs. E. D. Girdlestone's work is, on the whole, the best she has yet shown, especially "I'm a-weary, I'm a-weary" (239). Miss M. Silverston's best exhibit is a good portrait of Whitworth Wallis, Esq.; her portraits of ladies not being as good as in former years.

The work of Mr. W. T. Greatbatch is quite up to his standard, but we do not think that it is better than he has shown before. His best is "The Miller," who stands at his desk, against a window, a difficult subject, not quite mastered. Mr. Smedley Aston emphasises the departure he made a few years ago; and since giving up the soft, low-toned landscapes he then produced, has now gone to the opposite extreme, and is apparently influenced by the style of Rossetti and Holman Hunt, and the Pre-Raphaelites, in his portraits by photography, by selection of models and dresses and the use of Morris's wallpapers, small stops, and hard negatives.

Mr. W. A. Clark has many beautiful architectural interiors in which difficult effects of sunshine and shadow are well rendered. Mr. Arthur Marshall's "The Last Rest" (168), is, to our mind, the finest photograph in the whole exhibition. It is another proof, if it were needed, that technical perfection is no bar to pictorial perfection. The subject is not a specially difficult one, an Elizabethan tomb with recumbent figures, a plastered wall, and a stone column, that is all. But the clever massing of light and dark, and the rendering of textures (the alabaster with the polish of centuries, the broken colour of the plaster, and the masonry of the pillar), are masterly.

Mr. Page Croft's work is neither better nor worse than usual. "A Portrait Sketch" (33), is perhaps his best, the ghastly bluish-green colour of some prints seems most inappropriate for portraits. It is pleasant to be able to welcome some names of new comers. Mr. J. C. Batkin has several very beautiful "gum" prints of harbour scenes, with all the delicacy and detail one could desire, showing what an elastic medium "gum" is in the hands of those who know what they want. One wonders why Mr. Batkin's "Dutch Canal" (202) did not receive the medal, which fell to "Tugging Home" (193), by W. Clayden.

Another new comer, Ernest A. W. Moore, has a well nigh perfect picture in "Sad Memories" (18), an old man sitting in a church porch, the soft, grey light, and the little gleams of sunshine on the old man's shoulder are rendered in a tender and delicate manner that is delightful. In "The Gleaner" (58), Mr. Moore has been not quite successful, the pose of the figure and the background are charming, but the whole suffers by being too low in tone. "To the Altar, Wirksworth," by Percival W. Crane, is such a palpable "crib" of Mr. Bland's well-known picture as to be ludicrous, and the composition is very unsatisfactory. Mr. A. G. Peck's "The Snow Path" (243), is a glorious picture of large size, of sunshine and snow. It is most refreshing to see a successful rendering of bright light in these days of murky gloom.

J. Cruwys Richards sends some of his charming portraits, but none better than we always expect from him. In "A Woman of Conhemara" (309), he has been guilty of a piece of wickedness that we did not think he could have perpetrated, and the fact that it is so clever makes his crime the greater. It is a large head of an old woman in coloured gum. The clay-coloured face, the crude red shawl, and the pale blue background make one wonder how Mr. Richards could have done such a thing, and one feels if only the time and patience wasted on this work had been spent in producing monochromes what grand results might have been attained.

The Foreign Section contains some interesting work, and some extremely bad. The judges in this class awarded two certificates only. The Scientific Section is unusually large and good, and demonstrates how valuable photography has become to research workers. The Loan Section is small, but includes a fine series of Mr. F. H. Evans's cathedral photographs, some excellent work by Mr. Mummery, and some of the exhibits of the Salon Club of America. In this section there is a nude study, in which the pose of the figure produces a series of zigzag lines that are extraordinarily ugly. In the entrance room Mr. T. A. Sands's colossal enlargement cannot be missed, but its breadth and artistic effect suffer from being hung so low down.

LIST OF AWARDS.

Members' Section.—Bronze medal, Ernest Moore (18); certificate, E. W. Taylor (25).

Members' Section for those who have never taken an award or exhibited at the R.P.S. or Salon.—Certificate, J. B. Walker (305).

Open Section.—Silver medals, J. M. Whitehead (305); Mrs. Barton (two) (104 and 319c). Bronze medal—Arthur Marshall (168); William Clayden (193); A. G. Peck (243). Certificate—Miss Warburg (140); Arthur Marshall (185); E. Seymour (194); Dudley Hoyt (322); Karl Weiss (two) (365 and 370).

Lantern Slides (Open Section).—Silver medal—Niels Fischer; bronze medal—H. Wild; certificates—Neils Fischer and W. A. I. Hensler.

Lantern Slides (Members).—Bronze medal—W. A. Clark; certificate—W. A. Clark and W. F. Lewis.

Warwickshire Survey.—Silver medal—J. B. Walker (51 to 75); bronze medal—Thomas Clarke (1 to 50).

Scientific Section.—Silver medal—Percy Longmuir ("Photomicrographs"); W. M. Martin ("Embryology of Chickens"); Oliver G. Pike ("Studies of Birds"). Bronze—Dr. Rodman ("Radiographs of Shells"); W. Farren ("Reed Warblers"); W. Farren ("Caterpillar of Hawkmoth"); B. H. Bentley ("Wild Arum"); John Moore ("Studies of Snails"). Certificate—G. A. Booth ("Blue Tits"); B. H. Bentley ("Humble Bee on Sea Holly"); W. Heathcote ("Cole Tit Feeding Young"); Oliver G. Pike ("Garden Warbler"); W. Heathcote ("Young Starling"); J. Stabb ("Lightning Flash"); C. J. Watson ("Series of Oscillating Electric Sparks"); G. H. Booth ("Natural History"); B. H. Bentley ("Queen of the Air"); Dr. Thurston Holland ("Radiographs of Bone Diseases").

GLASGOW SOUTHERN PHOTOGRAPHIC ASSOCIATION.

The fourth annual exhibition of the Glasgow Southern Photographic Association opened on Tuesday last at the rooms, Eglinton Lane. The pictures are on view each evening until Tuesday, March 7, and a varied programme has been arranged for during the exhibition. The entries this year are far in advance of last, the total number of contributions being 408 as against 253 on the previous occasion. The judges were Messrs. A. Cochrane, J. W. Eadie, and Tom McEwan, R.S.W., who have had a task of some magnitude in making the awards. On Class 1 (open to all) there were 115 pictures, so that the judges made awards of three additional medals, making two silver medals—one to Fred Judge for "November" (256), a charming woodland picture, and one to A. C. Milne for "Of Highland Descent" (312). The bronze medals were three in number, and were awarded to Wm. Clayden, "Tugging Home" (237), a picture light in colour, suggestive of heat haze of summer; A. W. Hill, for "Mo Nighean" (242); and E. Seymour, "Flower Study" (274). Class 2—Lantern slides, flowers, etc. (open): Silver medal, E. Seymour; bronze medal, Robert Burnie; and certificate, W. H. Goy. Class 3—Lantern slides, any subject (open): Silver medals, Rev. H. W. Dick and Graystone Bird; bronze medals, Thos. H. Taylor and H. Wormleighton; certificate, Chas. Kirk. Class 4—

Any subject (confined to Federation associates): Silver medal, A. W. Hill; bronze medals, A. C. Milne and J. C. Robertson; certificates, M. Warnock, John Ritchie, D. M. Filshill, and R. Murray. Class 5 (members' work): Silver medal, Wm. A. Frame; bronze medals, J. H. Pollock and J. Waugh; certificate, Robert Ure. Class 6 (members' work): Silver medals, Robert Wallace and D. C. Murdoch; bronze medals, George Warkness and D. Linton; certificate, R. Lindsay. Class 7—Lantern slides (members): Bronze medals, Robert Ure and Robert Wallace; certificate, Wm. A. Frame. The pictures exhibited are above the average, and in the members' classes there are many pictures which the judges must have had some difficulty in passing over.

EDINBURGH PHOTOGRAPHIC SOCIETY.

The annual exhibition of the Edinburgh Photographic Society was opened on Saturday last, and will continue for the next three weeks in the Society's rooms, 38, Castle Street. The exhibition is divided into two classes—an open section, which is considerably the larger of the two, and a section restricted to members who have not previously won a medal at any of the Society's exhibitions.

The most outstanding figure study is one by A. Hamilton Allan, Edinburgh. It is the work of one who undoubtedly has a knowledge of art, and who has evidently studied in a Whistlerian school. A. W. Hill sends two gum-bichromate works, and the better of the two, which has been medalled, a head of a girl, is of remarkably fine quality, showing the value of this process that has not yet been taken advantage of by more than one or two Edinburgh workers. E. Drummond Young exhibits several good figure subjects, and James Burns, who has hitherto confined himself to landscapes, has scored with a portrait, "Marie," that embodies the latest principles of the advanced school of photography. J. C. Robertson, Brechin, exhibits a beautiful print of a little boy sitting beside the wreck of his toy engine. James Patrick has been medalled for a portrait of E. A. Hornell of excellent quality. J. B. Johnston shows an interesting bit of Old Edinburgh, and a street scene with figures that merited an award; and James Ashurst, Musselburgh, a new exhibitor, has won deserved commendation for his picture of "Where Men Toil." Other pictures of merit are shown by John Moffat, R. S. Webster, R. M. Readdie, E. Von Rosenberg-Lipinsky, and Allan Brothers, the latter exhibiting a winter scene that looks more like a chalk drawing than a photograph. In the restricted section mention may be made of two winter scenes by W. Mitchell, a landscape by W. J. Crear, "The Ferry," by J. M. Comrie, which has all the advantages of excellent mounting; and an old doorway by H. S. Harrison that might well have been medalled instead of receiving honourable mention. The following is a list of the awards made by the judges, Messrs. Robert Gibb, R.S.A., Gemmell Hutchinson, A.R.S.A., and Frank Sutcliffe:—

Open Section—Medals: A. W. Hill, Bank House, Shotts; James Patrick, Edinburgh; James Burns, Edinburgh; A. Hamilton Allan, Edinburgh; James Ashurst, Musselburgh; John Spark, Perth; J. C. Robertson, Brechin; and William Clayden, Plymouth.

Members' Section, restricted to those who have not previously gained a medal—Medals: Miss Agnes W. L. Dickie, W. J. Crear, Ewen Kennedy, and J. D. Paterson. Hon. Mention: J. M. Comrie, Charles Kean, G. G. Sutherland (2) Ewen Kennedy, A. E. Robertson, and H. S. Harrison.

BOWES PARK PHOTOGRAPHIC SOCIETY.

A very well arranged and creditable exhibition of members' work was held at the Unity Hall, Wood Green (the meeting place of the society), on February 23rd to 25th. Although the situation of the hall is quite away from the main thoroughfares the attendance each day was very satisfactory, and the financial success of the show, which is the second

arranged by this young and energetic society, seems assured. Mr. R. Child Bayley made the following awards:—

Class A (Landscape).—Bronze medal, A. J. Craston; certificate, H. C. Bird; ditto (extra), H. T. Parker.

Class B (Portraiture).—Bronze medal, W. J. Edmonds; certificate, R. Core Gardner.

Class C (Architecture).—Bronze medal, A. Kernon; certificate, W. J. Edmonds.

Class D (Still Life).—Bronze medal, H. T. Parker; certificate, E. Tappenden.

Class E (Lantern Slides).—Bronze medal, W. J. Edmonds; certificate, F. P. Bayne.

Silver medal for the best picture, H. T. Parker.

[Owing to pressure of space the list of *Forthcoming Exhibitions and Competitions* is unavoidably left over this week.]

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents were made between February 13 and February 18:—

PRINTING POSTCARDS.—No. 2,895. "A picture postcard printing frame." Claude Low, 54, Cockburn Street, Edinburgh.

SHUTTERS.—No. 3,162. "Means for setting roller blind shutters in photographic cameras by the introduction of a dark slide or the like." A. R. Lange, 73, Cheapside, London.

DEVELOPMENT.—No. 3,164. "Improvements relating to the development of photographic plates, films, and the like." W. F. C. Kelby, 7, Southampton Buildings, Chancery Lane; London.

APPARATUS.—No. 3,165. "Improvements relating to photographic apparatus." W. F. C. Kelby, 7, Southampton Buildings, Chancery Lane, London.

PRINTING FRAMES.—No. 3,192. "Improvements in printing frames." Louis Gritte, 4, South Street, Finsbury, London.

PRINTING POSTCARDS.—No. 3,296. "Improved apparatus for printing photographs from negatives, and more particularly for printing photo postcards." F. J. Seaman, Gough Chambers, Savile Street, Hull.

PRINTING FRAMES.—No. 3,375. "Improvements in printing frames." E. R. Petrie, 40, Chancery Lane, London.

LENSES.—No. 3,398. "Improvements in certain photographic and other lenses." H. Dennis Taylor, Buckingham Works, Bishop-hill, Yorks.

The following patents are open to public inspection before acceptance under the Patents Act, 1901:—
Nos. 1,594 and 1,595, 1905.—Lenses. Nehring.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W. C.

AUTOMATIC PHOTOGRAPHING TELEGRAPHS.—No. 29,428, 1904. Improvements in such telautographs or automatic photographing telegraphs, whereby the speed of the production of the several photographs at the receiving station can be increased with perfect safety, while it is possible to produce photographs not only from transparent originals, but also from opaque originals. The objects of the improvement are, first, to provide means at the sending station for feeding the several originals in a direction and for holding them one after the other in a stationary position for the exposition; second, to provide similar means at the receiving

station for feeding the several parts of an endless sensitive film or paper or the several sensitive plates, papers, or the like, and holding them one after the other in a stationary position for the exposure; third, to provide, both at the sending station and at the receiving station, either an endless movable band with a series of differently arranged apertures or a turntable disc with a series of apertures disposed in a spiral, these apertures being arranged for disclosing consecutive strips of the original or the sensitive film part, plate, paper, or the like, respectively, one after the other; fourth, to provide means for actuating synchronously the two endless movable bands or the two turntable disks at both stations; fifth, to arrange the rays of light emanating from the opaque original or passing through the transparent original at the sending station to pass through the consecutive apertures of the endless movable band or of the turntable disk for acting upon the radiophone; and, sixth, to arrange the intermitting rays of light at the receiving station to pass through the consecutive apertures of the endless movable band or of the turntable disk for acting upon the sensitive film part, plate, paper, or the like. Paul Ribbe, 140, Kurfürstendamm, Halensee, Berlin.

CAMERAS.—No. 4,831, 1904. The chief claim is for the special form of front shown in the figure. To the slotted standards, B, are attached pairs of arms, D and E, to which the lens board is attached. This combination thus acts as a universal swing-front,

and it also permits of the lens-board being brought close to the plate, the arms being then behind the standards, B. There is a special locking device for the arms and for the standard B to the base-board. R. and M. Ballantine, 101 and 107, Buchanan Street, Glasgow.

FILMS.—No. 24,774, 1904. A self-stripping film, consisting of sensitive emulsion coated on a compound film of gelatine and collodion, which is cemented to a highly glazed paper by means of albumen. During washing the albumen dissolves out, the negative thus detaching itself from the paper support. M. Bry, 32-34, Rue du Chemin du Fer, Courbevoie, France.

MESSRS. MARION AND CO., LTD., of 22 and 23, Soho Square, London, W., inform us that they will be holding their annual clearance sale from March 13th to 18th, both days inclusive, when many bargains in hand, field, and studio cameras, lenses, tripods, etc., etc., will be offered. Full detailed catalogues will be published a few days before the sale and may be had on application.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

March.	Name of Society.	Subject.

9.....	Hull Photographic Society	{ <i>Gum-Bichromate Printing</i> . Mr. J.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held February 28, Major-General Waterhouse in the chair. —A paper on "Control of the Development Factor at Various Temperatures," by Mr. W. B. Ferguson, K.C., M.A., F.R.P.S., and Mr. B. F. Howard, A.M.I.E.E., F.R.P.S., was read by the latter gentleman. The authors detailed the experiments made to determine the extent to which the development constants of a plate varied with the temperature, and explained the methods of plotting the results so that differences in temperature could be allowed for in practical work. Their work was done with a pyrogallol developer of strength 2 grains per ounce, and containing 1 grain of bromide per ounce. The tables obtained for each particular emulsion were found to hold good for a given batch for a considerable time, and one instance was cited in which no change was observed in a batch of plates in six months, during which time they were subjected to a double passage of the Channel. The authors suggested that makers should mark plates for time development, and in the after discussion Mr. J. Sterry exhibited a label from an Autotype plate-box, which bore indications of this kind, and was issued about ten years ago. The authors mentioned that they soaked both plates and films in water for one minute before commencing development. In some cases they found that this led to pinholes unless a stream of water was dashed vigorously over the surface. Some landscape lantern-slides

from negatives developed by calculated time were projected, and were received as the strongest demonstration of the soundness of the authors' methods.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.

MEETING held February 23, Mr. R. P. Drage in the chair.—A Paper on "Orthochromatic Photography" was read by Mr. A. J. Bull, and is reprinted on another page. Mr. Bull illustrated his many practical points with projection experiments, and showed the actual effect of filters, etc., for which formulæ are given in the paper. A brief discussion followed, in which Mr. W. Thomas, Mr. S. J. Beckett, the Chairman, and others took part.

GLASGOW AND WEST OF SCOTLAND P.A.

A PAPER on "The Capacity of the Different Printing Processes to Render Gradation" was read by Mr. Wm. Goodwin before the members of this Association on Monday last. Mr. Goodwin stated that his investigations were made to enable a comparison to be made of the different printing processes in daily use, and the character and extent of the gradations of the papers used. Some difficulty was found in getting a sensitometer or scale to measure the gradations, and he found one made of tracing paper from one sheet upwards to opacity proved most satisfactory. The range of gradation in plates and printing-out papers was shown to vary to a considerable extent with the different makes. There is little need, Mr. Goodwin stated, for using a variety of plates, as rapid plates may be used for all purposes. The dark-room lamp should be regular, so that density may not be faulty. Pyro stain deposited with the developer has a great influence on the result in printing from the negative, so that a freshly-prepared developer, and one that is non-staining in its character, should be used, and the worker should depend upon silver alone for the image.

SOUTHAMPTON CAMERA CLUB.

THE members of this club met on Monday evening last for the purpose of a lecturette competition. The winner was A. E. Henley, with an account of a trip "From Harlech to the Roman Steps," and G. T. Vivian was second with a tour round the recent exhibition representing "Old Southampton." The Club Committee have recently recommended to the members a scheme for a photographic record and survey of Southampton. For the present the old town is only to be treated, and it is expected that within the next few months much will be accomplished. It is intended that the collection of prints shall later on be handed over to the town authorities upon suitable conditions.

DEVONPORT CAMERA CLUB.

A DEMONSTRATION of "Tabloid Photographic Chemicals" was given, before the members of this club, by Mr. W. D. Watmough, of Burroughs, Wellcome and Co., on Tuesday last. He toned several lantern slides by the Ferguson copper toning method, and produced results from a cold brown to a bright red. He also toned several bromide prints by the same process. The chemicals used were ten per cent. solutions of potassium ferricyanide, copper sulphate, and potassium citrate, compressed into one tabloid. The lecturer then intensified half a negative, using tabloid mercuric iodide and sodium sulphite, and a metol-quinol developer, and a fine result was produced. He then demonstrated the reduction of the negative, first by ammonium persulphate tabloids, and then by potassium ferricyanide and "hypo," pointing out that in the use of the latter the shadows of the negative were reduced in a greater proportion than the highlights, whilst with the former the reverse was the case. By an intelligent selection of these processes, the effect could be regulated according to the class of negative required.

HULL PHOTOGRAPHIC SOCIETY.

"GUM-BICHROMATE PRINTING" was the subject of a successful demonstration, by T. Heaps, before the members of this society, on Thursday last. After explaining several leading workers' methods, the lecturer described his own system. He first of all soaked in bichromate of potass. solution (1 oz. to 10 oz. water) a sheet of cartridge paper (a penny a sheet), and said this was good enough to commence with, but Hollingsworth's non-absorbent paper was strongly recommended, and any others may be used which float. After it is thoroughly soaked, dry in a warm room away from daylight. Then take sufficient of a gum solution, made up of 1 oz. clean gum-arabic to 3 oz. water, strained until perfectly clean and clear, and mix with dry powder-colour to make a thin paste—vegetable black, venetian red, etc., or a judicious mixture of both was recommended. The colour must be ground very fine first. Coat the sensitised paper quickly with the mixture by the aid of a hog's hair varnish brush, and be sure to rub well into the paper. When thoroughly dry, it is ready for printing. A negative inclined to be thin is most suitable; and the exposure is about the same as that for fully-printed P.O.P., under a negative of similar density. If carried a little further, however, there would be no harm done. The gum paper must be dry; yet, if a veiling of the whites is required, i.e., no clear white paper in the highlights, much in this direction is possible by a slight dampness of the paper. The paper develops without attention in cold water, but it should be turned over at intervals, and can be hastened where necessary, or locally, by gently dropping or flowing a smooth, fine stream, or even a fine spray, of cold water on the surface. If much over printed, warm water can be requisitioned. Not more than one print at a time should be developed until a little skill is gained; and, on no account, must one print catch another during its very tender stage of development. When nearly dry much local work can be done with a fine camel's-hair brush. If it is thought fit to introduce figures, etc., or even clouds, from other negatives all that is necessary is to remove that portion where the addition is to come with the brush referred to, and, when dry, re-sensitise the paper; coat the parts for duplicate printing with the same gum and colour mixture, and print in figures or clouds, and develop again. Once the print is dry, nothing will remove that which has gone right through the process successfully; hence the necessity to brush away just where the additions are to come in its first semi dry state.

ACCRINGTON CAMERA CLUB.

An instructive lecture was delivered by Mr. A. W. Cooper, of Preston, to the members of this society, on Wednesday evening last. Mr. Cooper dwelt on the practical part of photography rather than the technical. He asked his audience to aim at impressing their own individuality upon the picture, as an artist would in his paintings, giving due attention to the composition of the subject, the matter of light and shade, correct exposure, the tonality of the prints, and the trimming of the same, all of which were necessary to distinguish a "picture" from a mere topographical record. He advocated as being nearly always essential the taking of the sky on a separate plate, it being very rarely possible to get both sky and landscape correct on the one negative.

CONSETT AND DISTRICT CAMERA CLUB.

The second annual exhibition of this society was opened last Monday, in the club rooms at Luton House, Consett. The exhibition embraced 35 entries from Federation members, 381 entries from the local members, and 75 exhibits not for competition. The awards were:—Class A.: Federation exhibits—Walter S. Corder, 1 and 2 (Federation plaque and certificate); A. S. Grettes, 2 (certificate). Class B.: Landscape and seascape—J. H. Courtney, 1 (silver plaque); E. Urwin, 2 (silver pendant); J. H. Courtney, 3 (silver pendant). Class C.:

Portraiture—Jesse Hall, 1 (certificate); J. H. Courtney, 2 (certificate). Class D.: Architecture—Jesse Hall, 1 (bronze medal); John Miller, 2 (certificate); W. E. Massey, 3 (certificate). Class G.: Genre—Jesse Hall, 1 (silver pendant); Thos. Duckworth, 2 (silver pendant). Class F.: Lantern slides (set of three)—R. Gardner, 1 (bronze medal); Jesse Hall, 2 (certificate); R. Gardner, 3 (certificate). Class G.: Postcards (set of four)—W. E. Massey, 1 (silver pendant); F. Summers, 2 (certificate); J. Miller, 3 (certificate). Class H.: Best picture in exhibition—E. Urwin, "An Old Shoemaker." Class I.: Best print taken on summer tours—E. Urwin, 1 (bronze medal); Jesse Hall, 2 and 3 (certificates).

LEEDS PHOTOGRAPHIC SOCIETY.

Mr. GODFREY BINGLEY, president of the Yorkshire Photographic Union, gave a lecture before the above society, on Tuesday evening last, entitled "Oxford and Cambridge." Mr. Bingley showed a large number of slides of the various collegiate buildings of the two University cities. Mr. Bingley, as a slide-maker, is well known; and a very noticeable feature was the presence of suitable clouds in all his landscape work. His method is to make half-plate negatives of clouds, and, by selection of the most suitable parts, print a number of cloud transparencies, masking the lower part of the plate. The landscape or foreground is next printed on another plate, and the most suitable cloud transparency selected. By means of Howard Farmer's reducer, and a camel-hair brush, the cloud portions overlapping the landscape are reduced away. The two transparencies are then bound together.

Commercial & Legal Intelligence

SCULPTOTYPE Company, Ltd.—Registered February 17. Capital £1,000, in £1 shares. Objects: To adopt an agreement with W. B. Kraft and F. Gartner for the acquisition of their rights in an invention for an improved process of producing relief photographs or the like; to acquire the interest of the said W. B. Kraft in an agreement, dated October 25, 1904, between the said F. Gartner and W. B. Kraft, whereby F. Gartner granted to W. B. Kraft the exclusive rights respecting the said patents for the United Kingdom, the U.S.A., and Canada, and to develop and turn to account the said invention. No initial public issue. Registered office, 31, Edgware Road, W.

DISSOLUTIONS OF Partnership.—Helion Co., manufacturers of photographic art papers. The partnership between Otto Hehner and P. Leuthardt-Thornton, under which the business under the style of "Helion Co." has hitherto been carried on at 11, Billiter Square, London, E.C., has been dissolved, and such business is now discontinued.—E. C. Scholl, jun., and Co.—Notice is given in the "London Gazette" that the partnership formerly subsisting between Emile Charles Scholl and William Tristram Auchinleck, carrying on business as photographic trade enlargers, etc., at White Cross Chambers, South Castle Street, in the City of Liverpool, under the style of E. C. Scholl, jun., and Co., has been dissolved by mutual consent. All debts due to and owing by the late firm will be received and paid by Emil Charles Scholl, who will continue to carry on the business on his own account under the same name.

COPYRIGHT of a Picture.—Franz Hanfstaengl v. W. H. Smith and Sons.—Judgment was delivered in this action, in which the plaintiff, an art publisher, asked for an injunction to restrain the defendants from printing, selling, or publishing any copies or colourable imitations of the plaintiff's copyright works, particularly "Nature's Mirror," by Paul Thurnman. The plaintiff alleged that the defendants had published in "Munsey's Magazine," in connection with a prize for advertisement-identifying, a picture of a young lady gazing into a pool of water, and this he contended was a copy

of "Psyche" as she appeared in his photogravures of "Nature's Mirror." He pleaded that the use of "Psyche" in such a connection was derogatory to the picture as a work of art. The defendants denied that the "Psyche" produced in "Munsey's" was the plaintiff's picture, or that they had infringed, or intended to infringe, his copyright, and pleaded that he had not suffered any damage. His lordship held that the plaintiff was entitled to a verdict with nominal damages. If plaintiff desired to protect his copyright he was bound to take action even in a trumpery case. There would be judgment for the plaintiff for one farthing damages, with costs.

THE first meeting of the creditors concerned under the failure re Charles Joseph Jones, photographer, carrying on business at 176, Upper Street, Islington, lately residing and carrying on business at 9, Rosebery Gardens, Rosebery Road, Wood Green, under the style of Jones and Co., was held at the London Bankruptcy Court on Monday last, before Mr. G. W. Chapman, Official Receiver. The Official Receiver, after dealing with the proofs of debt lodged, stated that the debtor commenced business in February, 1904, when he took the studio and business of a photographer at 176, Upper Street, Islington. Since December last he had been pressed by several of his creditors. He had been in the bankruptcy court on a previous occasion, as he was adjudicated bankrupt in the High Court on December 17, 1903, on the petition of a creditor. He was then carrying on business at 75, Essex Road, Islington. His liabilities under that failure amounted to £913, and his assets to £23, but they subsequently realised £58. No dividend had been paid to the creditors under that failure, and he had not applied for his discharge. All the fixtures and fittings on the premises were the property of his wife. The business was purchased in his wife's name, but he had conducted it, and she had allowed him to use the plant, etc., but she had never assigned it to him. He had not yet filed a statement of his affairs, but he hoped to do so in the course of a few days. He estimated his liabilities at about £130 or £140, and his assets nil. He alleged his failure to have been caused through bad trade entirely, and heavy expenses incurred in working up a business, there being very little goodwill attached to it when his wife purchased it. Eventually the estate was left in the hands of the Official Receiver for summary administration in the usual manner.

KREBS v. Fuerst.—In the Chancery Division, on Thursday, February 23, Mr. Justice Buckley heard the application by defendants in the case of Krebs v. Fuerst Bros. for further directions on a procedure summons. The action was brought by Dr. Krebs, who traded under the style of Photochemische Fabrik Helios, Offenbach, against the defendants, Messrs. Fuerst Bros., Philpot Lane, London, upon an agency contract by which Helios transferred to Fuerst Bros. the sole right in the whole of their products except patented developers for Great Britain, Ireland, and the Colonies for a period of five years from September 1, 1901, to August 31, 1906. Fuerst Bros., on their part, covenanted to represent the interests of Helios to the best of their ability, and undertook that they would not, during the continuance of their contract, represent any competing factory with the exception of J. Hauff and Co. (a German limited company). The plaintiff determined the contract, owing to alleged breaches by the defendants, by a letter dated December 31, 1903. There were certain articles manufactured—sensitisers, developers, intensifiers, and reducers—as to which he alleged the defendants had broken their contract, alleging that they had deliberately and systematically pushed the sale of such goods produced by competing manufacturers to the exclusion of the goods of the plaintiff, and that they had also advertised and pushed the sale of, and had kept a wholesale depot for, photographic chemicals of the firm of Burroughs Wellcome and Co., besides breaking their covenant in three ways. Consequently they

had in their action claimed a declaration that the contract had been duly determined, and that plaintiff was no longer bound to employ defendants as his agents. He asked also for an injunction restraining defendants, for an account of profits, and for damages for breach of duty. The defendants, by the defence put in, denied the breaches, and contended that plaintiff had no right to determine the contract. The defence was also accompanied by a counterclaim against the plaintiffs. His lordship said the summons would be dismissed, the costs to be the plaintiffs' costs in any event.

News and Notes.

EDINBURGH Society's Dinner.—On Thursday last the annual dinner of the Edinburgh Photographic Society was held in the Carlton Hotel, Edinburgh. About fifty members and friends attended. The president, Mr. J. Tudor Cundall, B.Sc., presided.

THE sixteenth annual exhibition of the South London Photographic Society will be opened by the Mayor of Camberwell to-morrow (Saturday, March 4), at the Camberwell Baths, Camberwell Green. Doors open at 4 o'clock, ceremony at 8.

THE Cripplegate Photographic Society is arranging an historical exhibition of old photographic apparatus, prints, etc., and the secretary asks any one who is willing to lend such things for exhibition from March 20 to 23 to communicate with him. The society will pay insurance and carriage both ways. The secretary is J. B. Parnham, 5, Reighton Road, Upper Clapton, N.E.

THAT photography is steadily gaining ground as a means of education to the masses is evidenced by the fact that seven stereoscopes have been placed in Mile End and Limehouse public libraries, and a large number of views on educational subjects provided. These will be issued to the public in the same way as books. The idea is to stimulate local knowledge.

THE Watford Photographic Society's second annual exhibition will be held at the Watford Public Library, on Friday and Saturday, April 28 and 29, 1905. The judges will be the Rev. F. C. Lambert and T. Percivale Padwick. In addition to the members' classes, there will be a local class open to any amateur residing within ten miles of Watford. Entry forms can be obtained of the hon. secretary, C. J. Trevarthen, Ashcroft, Bushey Hall Road, Watford.

EASTMAN KODAK COMPANY OF NEW JERSEY.—The Kodak Co. write: "We beg to inform you that the usual quarterly dividends of 1½ per cent. (being at the rate of 6 per cent. per annum) upon the outstanding Preferred Stock, and of 2½ per cent. (being at the rate of 10 per cent. per annum) upon the outstanding Common Stock, have been declared by the Eastman Kodak Company of New Jersey, payable on April 1, 1905, to stockholders of record at the close of business on February 28, 1905.

THE Queen of Italy has honoured Messrs. Speaight, of 157, New Bond Street, W., with a commission for a "Baby's Album" for the little Italian heir. The book, which has just been sent to Rome, is beautifully bound in blue art linen and vellum, and its title page has spaces reserved for the names of King Edward, the Prince of Montenegro, Queen Margherita, and the Emperor William, who were the chief sponsors at the recent christening. Four pages in the book are reserved for interesting events in the Prince's life, and there are twenty-one blank pages left in order that the child's portrait, together with an autograph, may each year, until he comes of age, be kept on record.

PHOTOGRAPHIC Survey of North Middlesex.—The Record Committee of the North Middlesex Photographic Society are seeking co-operation in undertaking the photographic survey of North Middlesex. Among the objects most desirable to record are old buildings, lands, roads, streams, bridges, etc., having any particular local interest, or likely

to be removed or interfered with, especially the old rural architecture of the county, together with old furniture, fittings, implements, etc. Particulars of the record work are exhibited in the club meeting room, and any further information will be given by Mr. J. C. S. Mummery, F.R.P.S., hon. secretary to the committee. His address is 81, Pellatt Grove, Wood Green, N.

BLAIRGOWRIE and District Photographic Association.—The annual general meeting of this association was held in the club rooms on Tuesday evening last. The hon. sec. (Mr. L. Falconer, jun.) reported a successful year, and the treasurer's report showed a satisfactory balance in hand. Office-bearers were elected as under:—President, Mr. Geekie; vice-presidents, Messrs. J. Deuchars and H. D. Ross; secretary, Mr. L. Falconer, jun.; treasurer, Mr. John Cameron; auditors, Messrs. J. M. Donaldson and D. S. MacLennan; hon. lanternist, Mr. H. S. Pyffe; executive, Messrs. MacLennan, J. Richardson, J. D. Petrie, W. D. M. Falconer, and J. B. MacLachlan. It was agreed to continue affiliation with the Scottish Photographic Federation.

PARCEL Post with the United States.—The agreement for an official parcel post between this country and the United States of America, which has been signed by Lord Stanley and the Postmaster-General of the United States, will be of special interest to many photographers and dealers in both countries. The following is the text of the official intimation:—"The new service will be established on April 1 next. The limit of weight for parcels from the United Kingdom will be 4 lb. 6 oz., and the postage will be 2s. for each parcel. There will be no non-postal charges apart from Customs duty. The insurance system will not apply to parcels sent by the new service. This official service will, however, be carried on concurrently with the semi-official service at present maintained through the agency of the American Express Company, by which parcels can be sent up to 11 lb. in weight, and can be insured for any value up to £120.

THE King under Fire.—The Press photographers at Portsmouth, during the visit of His Majesty on Tuesday, had a unique opportunity of showing their mettle, and doubtless there was subsequently much competition in getting prints off to town in time for this week's illustrated papers. After completing the inspection of H.M.S. Drake, and successfully dodging the photographers who were tracking him all the morning, His Majesty gave his tormentors their opportunity. Officers of all grades, from flag-captain to cadet, took up positions. In front stood the King, with Prince Louis on his right and Admiral Fisher on his left. When half a dozen civilian and naval photographers had placed their cameras in position, His Majesty, first inquiring: "Are you ready?" gave the command "Fire!" The photographers "fired," and notable pictures should be the result.

A New Copying Accessory. Made by the Tress Co., 23, Oxford Street, London, W.

An attachment which serves the useful purpose of moving a print to and from the lens exactly at right angles to the axis of the lens is sure of a welcome at the hands of both amateur and professional workers. In the form in which it is made by the Tress Company, it consists of a stout mahogany bar, which is screwed to a table or studio tripod with an ordinary sewing-machine clamp. Within the bar slides a second one, on which the print, be it carte-de-visite or 12 by 10, is mounted in such a way that it can be brought opposite the lens of a large or small camera, and can be moved steadily to and fro as the operator watches the focussing screen. The attachment thus renders easy and rapid the task of copying or enlarging a print without special apparatus, and it might be used also in making lantern-slides by reduction. Its price is 10s. 6d.

Correspondence.

- * * *Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given.*
- * * *We do not undertake responsibility for the opinions expressed by our correspondents.*

COPYRIGHT IN THE TRANSVAAL.

To the Editors.

Gentlemen,—Can you inform me whether a photograph copyrighted in the Transvaal is protected in England? There seems to be some doubt on the matter, and to be certain I am sending you some photos for registration in London which I have already registered here.

The copyright law here is most unwieldy and expensive, and as far as I can gather does not include Cape Colony, Rhodesia, or Natal. In the Transvaal you have to make a sworn declaration before a J.P., and affix a 2s. 6d. revenue stamp. Then you interview the Registrar of Deeds and affix a further 10s. revenue stamp, and attach three copies of the photograph with your name, address, and date written across the front. When this has to be repeated in three other colonies in order to have a South African protection, it is no wonder that photographers prefer chancing piracy. Can nothing be done towards simplifying matters by arranging an Imperial Copyright Union between British Colonies and England, so that by registering a photo in the Transvaal, Australia, Canada, or any other British Colony, protection would be extended to the whole of the British Empire. I should think that the subject should be taken up by the Photographic Copyright Union, for it is of considerable importance to all professional photographers.—I am, yours faithfully,

R. C. E. NISSEY.

P.O., Box 453, Pretoria,

February 6, 1905.

[The Transvaal and the Orange River Colony having become part of the British Empire the terms of the Berne Convention, under which Great Britain and Ireland, "and all the colonies and foreign possessions of Her Britannic Majesty," are made members of the International Copyright Union, apply to these countries.

Under the Convention registration of copyright in any one subscribing country or colony, makes the work legally copyright in all the other subscribing colonies. But the formalities of the country of origin must be observed, and our correspondent's very legitimate grievance had therefore best be addressed to the authorities at Pretoria or Cape Town. We believe the state of the copyright laws in South Africa was the subject of organised protest some time ago from the Cape Town Photographic Society, and possibly the officials thereof can say what was done in the matter.—EDS. B. J. P.]

THE SLACK SEASON.

To the Editors.

Gentlemen,—In many small towns the slack time extends over a period considerably greater than the one generally assigned to it, and it must be a difficult matter for many photographers to tide things over. We hear about benevolent associations, but there is a good (or bad) old maxim: "Every man for himself and . . . I will leave it to your readers to fill in the blanks. But it is a fact that when things are bad some of us need not shrink from making the proverbial honest penny in other ways. Many do so, I believe. I know I can vouch for the following cases that have come before my notice: One photographer, now in business in my locality, has held the place of verger in a parish church for some years past; another has found his musical ability stand him in good stead; when his business declined he obtained a permanent engagement in a theatre orchestra, that fully made up for his loss in trade. Two others, not so fortunate,

have taken on waiting at table in gentlemen's establishments to augment their incomes, and thus make up for the depression in their businesses.

This sad state of things should prove a lesson to our coming assistants, and induce them to take advantage of their spare hours in acquiring a knowledge of some other work, they can fall back upon in the event of photography failing to bring them in a living.

The benefits to be derived from a course of instruction in drawing, shading in chalk, and monochrome have been pointed out in the B.J., and I hope you won't think me an egotist, but I can speak from experience on this matter, and can truthfully say, the knowledge I acquired in these subjects has been the means of adding to my income apart from my business in photography; and it has been a pleasure too. For instance, I took on illuminating and writing mounts—such as are done in university towns—writing and embellishing fly leaves of scrap books, etc., with painted crests and coats-of-arms; now and again a presentation address fell to my lot, and occasionally I have turned my hand to illustrating verse, with fair success. But in this latter branch photography comes in useful; to give a simple proof, matt-surface paper prints are traced over with specially prepared Indian ink, so that it withstands the action of water; the photograph after this operation is dissolved away, leaving a rough outline sketch, that often does for the purposes of reproduction.—

UNIFOD.

A FORTY-PAGE list from Mr. Jonathan Fallowfield is the outward and visible sign of a bargain sale which he is holding at 146, Charing Cross Road, London, W. The sale lasts until March 20. An immense variety of apparatus and materials is offered at greatly reduced prices, and the occasion is one which many will probably embrace, as it is not every day that one can pick up useful accessories at the prices which we see in the list. To select only one or two items:—A stamp camera for twenty-five pictures on the 7 by 5 plate is priced at £6 6s. A "Nydia" hand-camera for £6, and a bewildering variety of mounts in 100 and 1,000-lots at low prices. The firm guarantees the first-class working condition of the goods, and the list distinguishes between the slightly-soiled or out-of-date articles, which chiefly make up its contents, and actually damaged goods.

LIVERPOOL Photographic Trade Association.—At the first annual dinner of the Liverpool Photographic Trade Association, Mr. F. V. A. Lloyd, who presided, referred to the depression of trade from which he said all of them must have suffered to some extent; he was, however, optimistic enough to believe that they were on the eve of improvement, and he predicted an exceptionally good business year. The speaker briefly referred to "the concentration of forces, which is daily taking place in the photographic trade," and it was for them to consider whether the developments resultant therefrom were for the benefit of the retail dealer. There were two questions to consider. (1) Do the general public want such value as the manufacturers are now placing on the market? and (2) are the present cutting of prices and showy improvements of apparatus a gain to the trade? To both of these queries a negative answer could, in his opinion, assuredly be given. They all desired to have strong wholesale houses full of energy, inventiveness, and progress, but there was no reason why competition should allow the wholesaler to overstep the limit. Much depends on the retail dealer, and he must not forget the important part he plays in the business world. Their unity of purpose combined with good feeling was of so much value that no power, however strong, would deem it wise to pay anything but deference to the Association or its members. It was for these reasons that he should like to see other large centres following their example, and so greatly benefiting themselves and strengthening the retail photographic dealer throughout the country.

Answers to Correspondents.

- * * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- * * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.
- * * * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

- J. J. Wright, 125, London Road, King's Lynn. Photograph of Proclaiming Kings' Lynn Mart.
- Morrison & Ednie, 28, North Bridge Street, Edinburgh. Photograph of J. Lindon, Esq., M.D.
- S. G. Beach, Fir Glen, Dartnell Park, West Byfleet. Photograph of the Rev. W. F. T. Hamilton.

- T. B. Lachmore, 11, Brand Street, Hitchin, Herts. Photograph of the "Old Trooper" Public-House at Hitchin.
- F. Weisner, 59, London Road, Liverpool. Two Photographs of "La Marguerite."
- D. Ross, Norman Place, Leslie, Fife. Photograph showing Kinnesswood, Lockleven and Benarty Hill. Photograph showing Loch Lomond and Bishop Hill.
- J. Allan, 208, Firthill Road, Glasgow. Photograph of H. A. Long Lecturing at Glasgow Green twelve years ago.

H. G. CONYBEARE.—See reply to "W. R."

W. F. B.—Not by you. You have our congratulations in one respect.

PLATINUM.—Probably sensitising salts, ferric oxalate, or double oxalate of iron, sodium or ammonium.

A. F. VILLIERS, Bristol.—Jonathan Fallowfield, 146, Charing Cross Road, London, W.C.

J. W. E. (Caerlinion).—The Pocket Photography Company, 56, Gracechurch Street, E.C.; and The Quincey P.D. Company, 136 and 138, Kentish Town Road, N.W.

FERROTYPED PLATES.—Should be obliged if you could give us the name of any good maker of ferrotype plates.

Try James Moore, 258, Heneage Street, Birmingham.

W. ANDERSON.—We certainly cannot publish the copy of your letter, particularly as you do not send the reply you received to it. We do not see that you have very much to feel aggrieved at after all. We should advise you to take a broader and more liberal view of things generally.

ADDRESSES.—Will you kindly answer the following questions in the B.J.P.?—(1) The address of the makers of the Bastian light.

(2) The address of the Luxia Company.—W. R.

(1) Rumney and Rumney, 39, Victoria Street, London, S.W.

(2) South Hill Works, Hampstead, N.W.

H. E. M.—We cannot accede to your request, although we sympathise with you in your misfortune. But in dealing with strangers you should obtain satisfactory references, or avail yourself of the deposit scheme which our publishers maintain for the protection of advertisers. Conditions of deposit will be found on page 2 of each week's issue.

S. E.—A suitable toning formula for bromides, which will give very much the same tone as that of your sample is: Bleach the prints in a solution of potassium ferricyanide (half an ounce), ammonium bromide (300 grains), in water (20 ounces), and after well washing darken in a solution of pure sodium sulphide (30 grains in 10 ounces), and again wash thoroughly.

WANTED. A RAPID PROCESS.—May I beg you to advise me on a process whose characteristic should be simplicity and quickness? I want to start taking photographs of people on postcards (can

such a thing be done direct, without making a negative first?), to be delivered within a few minutes.—J. GANDE.

Direct positive work, on paper, is not a practicable process. We think your requirements will be met by the ferrotype form of photography. Write for price lists and particulars to Jonathan Fallowfield, 146, Charing Cross Road, London, W.; and to the Quta Machine Company, 34, Norfolk Street, London, W.C.

COPYRIGHT.—I have taken a photograph of a professional music-hall artist free of all charge to same. The photograph has been given away at two halls as souvenirs. Will you kindly tell me if I am entitled to a reproduction fee from the printers', if so how much?—A. S.

You are entitled to a fee. If you have not done so you should register the copyright, and then demand the withdrawal of the souvenirs from circulation, at the same time asking for settlement as regards the copies already issued. You may claim from the printers or from the agent of the artist, for whom, probably, the printer has executed the souvenirs.

LENSES.—(1) Recently I sent a R.R. lens to a gentleman on approval. He returned it, with the complaint that "it was insufficiently corrected for landscape work." Now, as I know the lens works true to focus on printed matter please explain what he means, and kindly give me a test that I may verify whether it is so or not for myself.—OTHELLO.

(1) Your correspondent's objection is probably disingenuous. If the lens will photograph printed matter sharply that is a good enough test, if it is for landscape. About the best way to make the test is to focus newspaper printing, pasting several columns together so that when the width of the column is about half an inch on the focussing screen the length extends from end to end of the plate. Focus in the centre and then compare the definition at the edges. If the screen has to be moved nearer the lens to get the margins sharp, make a note of the distance. It should never be more than three-quarters of an inch for an 11-inch good R.R., and in this proportion for smaller or larger focal lengths. (2) 13, Old Grange Road, Sparkhill, Birmingham.

COPYRIGHT INFRINGEMENT.—I photographed an old gentleman two years ago, for which no money whatever has been paid. He came to be seriously ill about two months ago, and seeing this I copyrighted the negative. In about three weeks after I saw my copyright infringed in a local paper as an advertisement for a firm of pills. They have reproduced without my permission. Can I claim compensation, and if so, what amount? I may say the old gentleman had several pictures off the negative, but I am almost certain it is from a print I gave him after I copyrighted the negative that the reproduction was made. Is it necessary to have the word "Copyright" on a print to protect it, as I did not mark the mount? What do you advise in the matter? Please give address of the Copyright Union.—PROFESSIONAL.

You have a clear case for action, it seems to us, as presumably no payments have been made to you by the sitter. Your best course is to write to the firm of advertisers, asking what compensation they suggest. In the meantime, the Copyright Union, 23, Soho Square, London, W.C., or the Professional Photographers' Association, 51, Baker Street, London, W., would advise you on your becoming a member. There is no necessity to have the word "Copyright" marked on the print or mounting.

SHUTTER, BROMIDES, WATER-COLOURS.—(1) Does not a Thornton Pickard 3-inch roller blind shutter work with a greater speed than indicated, if I place a smaller lens, say of a 1-inch diameter in front? The shutter is behind-lens pattern. As far as I can judge the shutter's speed is nearly double if used with

half plate lens instead of 9 by 7 lens. (2) If I remove or bleach out anything on bromide print with pot. ferricyanide, will it appear again, or will the bleaching be permanent? I only use pot. ferricyanide to bleach out small portions of print and get entirely rid of yellow stain with a weak solution of soda sulphite. (3) Does gum impair the stability of water-colour if mixed with them for colouring purposes? I mean ordinary office gum.—VELOCITY.

(1) The time during which the lens remains fully open will be a little less in the case of the half-plate, but the difference cannot be as great as you name. (2) The image will probably reappear on exposure to light, as the ferricyanide which is formed is slightly sensitive. Better use the iodine-cyanide reducer made by adding a few drops of 10 per cent. solutions of potass cyanide and iodine (the latter in spirit) to an ounce of water. (3) Ordinary office gum very probably would act prejudicially, but a solution of pure gum arabic can be used with safety.

COPYRIGHT.—Will you kindly inform me what you think of the following treatment, and if I have any redress re same. The summer before last I had an order to take a 12 by 10 group, 42 sitters in group. The photo was simply taken by appointment. I was not paid for taking same, simply sold the prints as ordered (and I sold a good many), and am sorry now I did not make it copyright at the time. My grievance is this, and I shall be glad of your advice re same. A tradesman here, that dabbles in photography, etc., sent his son for an unmounted print of said group. Never said anything about reproducing it, etc. The next thing I see is that same group reproduced, as post cards, and the man has been selling them since last summer. He has not even had the courtesy to ask my permission, or put my name on the post cards as the author of the photograph. If the man had had the decency to ask me my permission I would not have minded so much, but to be ignored in such a manner is not English. Your opinion re such treatment will greatly oblige. Also if I have any power to prevent his selling any more.—NEMO ME IMPUNE LACESSIT.

The treatment is certainly unneighbourly. You now find yourself in the same position that many others have done who have neglected to register the copyright in their photographs. Had you done that in the first instance you could have stopped the sale of the copies and obtained penalties for every copy sold, as well as damages, etc. If you register the copyright now you can prevent further sale, and recover damages for anything done after registration, if you can prove any, but not for anything done before.

NOTICE.

Several replies are held over for insertion next week.

NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

The British Journal of Photography.

The Oldest Photographic Journal in the World.

ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWOPENCE.

EX CATHEDRA.

Process at South Kensington. An official announcement has at last been made as to the opening of the long-expected Exhibition of Process-engraving at South Kensington. Even now the information reaches us, not from the authorities, but from a private person in the country, to whom the exhibition will be indebted for the loan of certain historical examples. In cherishing their bright designs remote from the public eye, the board of management may have some motive, but we should have thought that there was good reason for making the exhibition known through the technical Press. However, we can say that a private view will be held on March 14 from 10 to 10 in the galleries of the Indian Section (Imperial Institute Road) of the Victoria and Albert Museum, and presumably the Exhibition will be opened to the public a day or two later.

The Advent of Spring Light. Photographers, in and outdoor, do not need reminding of the greatly improved actinic quality of the light of the last two or three weeks. The improvement has not been great, it is true, but still it is an improvement. There are many photographers whose dark-rooms are illuminated by natural light, filtered through different-coloured media. Many, indeed most, of these are not stable so far as the colour is concerned; it fades with continued exposure to strong light. The fading is, however, so gradual that it often is not recognised or even suspected until actual trouble arises. Last summer was an unusually brilliant one, and produced fading in many of the fabrics on darkroom windows, but this did not matter much during the winter months when the light was feeble in actinism. But the case will be different when the light still further improves, as it will do during the next month or so.

The Dark-room Light. Therefore photographers who employ natural light in their dark-rooms will do well to look to the window without delay. It has just been said that the change in the fabric is so gradual that it is not realised until trouble arises—say, in foggy plates. But it may be manifest before that in the form of negatives with impaired brilliancy, and for this the plates may be blamed, though they are quite innocent in the matter. One of the most pleasant lights to work in is that filtered through the thick paper known as canary medium. Two thicknesses of that, on the pane of a window facing north, is perfectly safe, even with rapid plates, if they are not exposed close to it. Of course it will not answer with orthochromatic plates, and, unfortunately, the colour is not permanent. The same may be said of most coloured fabrics; therefore all of them should be looked to on the advent of spring, so as to avoid trouble in one form or other.

Trick Cinematograph Films.

Straightforward cinematograph pictures—unless they record some event which is the topic of the moment, bid fair to be driven from the field by the trick film, on which all the art and paraphernalia of a stage manager are now expended. The French cinematographists appear to take the lead in producing pictures of this description, and the effects which they obtain by interrupting the exposure of the film or by joining several bands of films, are a kind which evidently exactly suits the taste of the patrons of the "variety" order of entertainment. At London's greatest palace of amusement, the Coliseum, a trick film, obtained by one or the other of these simple methods, is an evident source of delight and astonishment to the audience seeking entertainment undiluted with instruction, and we must confess our admiration of the cleverness with which a whole series of incidents are pictured so as to appeal to one's senses of the sensational and the ludicrous, without a single word being spoken.

History, Second-hand.

As a specimen of such triumphs, a recent film may be instanced, in which are depicted the escapades of the reader of a thrilling narrative, concluding in the passage over him of a steam-roller, and the subsequent inflation of his flattened body by some passing cyclists! But the artist behind the cinematograph is not content with such achievements as this. His motto is "history repeats itself," or, rather, elaborate steps are taken to repeat it. A correspondent sends us a graphic account of his visit to a cinematographic studio last week during the production of a film showing the assassination of the Grand Duke Sergius. The arts of the costumer and the scene-painter

were applied to the reproduction of a realistic "mise-en-scene." The equipage of the Grand Duke drives up before the camera, the assassin throws his bomb, a bottleful of nails, and a fuse is fired, enveloping the group in smoke. The camera is arrested whilst broken wheels, shattered woodwork, and other debris are placed in position, and then the remaining scene in the drama is enacted. One cannot call such pictures frauds, for surely the most ignorant do not believe them to be actual photographs of the incident.

The Radio-activity of Mercury Compounds.

That the distribution of radio-activity is much more general than was at first supposed has been conclusively proved by the ever-increasing number of substances that have of late been proved to possess this property, and at a recent meeting of the Chemical Society, Messrs. Fleming-Struthers and Marsh reported that a compound of mercuric cyanide and phenylhydrazine was particularly active, giving, even in a few hours, a deep black patch, on development, through an interposed perforated zinc screen, wrapped in paper, and also at some distance from the plate through aluminium foil, though quartz completely stopped the radiation. Phenylhydrazine itself was sluggish in action, and only some samples of mercuric cyanide showed radio-activity. The mercuric chloride and bromide were active, as well as the mercurious and mercuric nitrates: the iodide, sulphate, acetate, sulphide, oxide, and mercuric ammonium chloride showed no action, or only a slight one. Re-distilled mercury showed no action.

* * *

Illegal Use of the Word "Royal."

We have more than once called attention to the fact that some photographers use the Royal arms and style themselves photographers to the King or members of the Royal family, while it is illegal for them to do so. The mere fact that they may have supplied photographs to the Royal family, or even if they have photographed the King himself, does not entitle them to use the Royal arms; they must first obtain the Royal Warrant to do so. It may not be generally known that it is illegal to use the word "Royal," as applied to anything, without a licence from the Secretary of State. In a case, tried one day last week in the Clerkenwell County Court, the Judge was evidently unaware of this fact, for he said: "There is no right to use the Royal arms without authority, but I do not think that applies to the word 'Royal.'" He was, however, corrected by the solicitors present. One said that from inquiries made at the Home Office he found that no person was entitled to use the word "Royal" without licence from the Secretary of State. We know that the word is freely used by some photographers, for example, "Photographer Royal," "Royal Studio," "Royal Portraits," etc., and they may not be aware that they are acting illegally.

Depression in Illustrated Journalism.

Sir William Ingram, in his speech to the shareholders in the "Illustrated London News" Company, dwelt at some length upon the recent falling off in the profits earned by periodicals of this class. He ascribed this falling off to the general depression which has for some while past hampered all sorts of artistic activity and to the unfavourable conditions under which art publishing is now being carried on. Our contemporary the "Globe" pertinently inquires "whether the management of certain of these papers is not quite as much the cause of their want of success, and whether the growing

tendency to substitute in them reproductions of commonplace photographs for the work of competent illustrators has not disgusted a large section of the people who used to support artistic publications." We do not think this is altogether the case. What the proprietors and editors of illustrated journals seem to forget is that there has been recently an enormous increase in the number of cheap publications which issue good reproductions of what may reasonably be called works of art, while their anxiety to be the first in the field with photographic representations of current events often leads to results that compare very unfavourably with the more artistic productions of the black-and-white artist.

* * *

The Bolt Court School of Photo-Engraving.

The narrow courts and alleys which make Fleet Street the delight of the American visitor contain much active industry compressed in the minimum of working space, but few establishments can show a better record of opportunities utilised than the London County Council School of Photo-Engraving, which pursues its useful work in its old-fashioned premises in Bolt Court. The annual report, just issued, states that the number of students in the art and photo-mechanical classes during the last session was only two short of 400, as compared with 245 in the year 1902. Four medals have been awarded to the work of the students in international exhibitions, and a considerable volume of experimental work of direct educational value has been published by the staff, aided by the senior students. The report itself—a handsome book of reproductions in the various descriptions of "process"—is about the best testimonial which the teaching staff can obtain, and it would seem that before many more are issued No. 6, Bolt Court will be quite unequal to providing accommodation for its students. It is to be hoped that the London County Council, in the midst of its large schemes for the government of London, will not disregard the needs of an institution which, in the eyes of the illustrating craft, has the most pressing claims upon its consideration and exchequer.

Colour Photography on Paper.

Dr. König describes in the current number of the "Photographische Mittheilungen" a process for obtaining prints in natural colours, which is the exact antithesis of the process of Lumière, Sells, and Sanger Shepherd, in which a bichromated gelatine film is exposed under a negative, and then the soluble portions washed away, leaving an image in hardened gelatine film that is subsequently stained and used to transfer the colour to paper. In "Pinatype," by which name Dr. König calls his process, a bichromated film is used, and after exposure under a transparency is soaked in special solutions of dyes, so that the soluble gelatine, or that unaffected by light, absorbs the dyes and again gives them up to paper. This is practically, then, an application of the well-known hectograph principle. The original plates can be repeatedly used, and it is obvious that it would be possible to obtain large prints by making enlarged positives and using these for printing. The details as to the making of the original negatives and printing in the complementary colours are the same as in the other processes. It is stated that the results are extremely sharp and clear, and that some of the results have been exposed to day and sun light for three months without showing any change of colours, therefore there is reasonable hope of their being permanent even in the more brilliant light of summer.

The Metric System.

It was but cold comfort that the advocates of the universal adoption of the metric system received from an answer to a question given by Mr. Balfour in the House of Commons one day last week. He said he did not see his way at present to propose a measure for the compulsory adoption of the metric system in this country. The use of that system, he added, was legalised for all purposes some years ago, and it was therefore open to any person trading with foreign countries to make use of it. If the metric system were universal among photographers, it would prove a great convenience, seeing that we get so many formulæ from the Continent, and they are all given under that system, also that they frequently suffer in the translation into English weights and measures, particularly when small quantities are concerned. One of the reasons why the system is not more generally used by those who practise photography is, no doubt, as we have said on former occasions, the difficulty in obtaining the weights and measures at a moderate price. Few dealers stock them, and if they are ordered specially, fancy prices are charged for them. There is no reason why either the weights or the measures should cost more than those under the English system. Indeed, on the Continent they cost, if anything, less. Until metric weights and measures are put upon the market by photographic dealers at a moderate price, we fear there is but little prospect of the metric system becoming generally adopted in the near future, desirable though it be.

THE COLLODIO-CHLORIDE PROCESS.

On another page our contributor "Historicus" deals with the first introduction, now forty years ago, of the collodio-chloride process by the late Mr. G. Wharton Simpson. Our friend would rather have us infer that the process as first introduced by its inventor was somewhat different from the collodio-chloride process of the present day. It is, however, practically the same. It is true that in Simpson's first formula there was no citric acid, though at the meeting at which the process was described the use of a citrate in the emulsion was suggested by one of the members present. A few weeks later, May 3, Mr. Simpson read a paper before the North London Photographic Association on his process for producing pictures on opal glass, and gave a formula for it. The formula stands thus: "To each ounce of collodion are added nitrate of silver ($7\frac{1}{2}$ grains), chloride of strontium (2 grains), citric acid (1 grain)." This formula, it will be seen, is just about the same as that given in all modern text-books for a collodio-chloride emulsion. "Historicus" refers to the greater permanency claimed for the process, which may be said to hold good. "There is no insoluble silver compound formed like that formed with albumen." We remember seeing in the photographic section of the Victorian Exhibition at the Crystal Palace, in 1897, some collodio-chloride prints by Mr. Bruce, who used the process exclusively in his business, which had been made for something like thirty years, and they were certainly as good as they could have been when first produced. Within the last few years, since the process has come into more general use, we have heard complaints of lack of stability in the prints, and the question is this: Is this due to the process itself, or the modern methods of preparing the paper or of using it? In the early days of the process the raw paper employed was the same paper as was employed for albuminising, and it received a coating of arrow-root, and on this the emulsion was applied. In modern practice raw papers of a cheaper kind are used, and they are surfaced—i.e., "baryta" coated. But it must be kept

in mind that a cement of some sort is necessary to secure the pigment to the paper. As the emulsion contains a certain amount of free nitrate of silver, some of this may, and does, combine with this organic matter, as may be seen if the collodion film be stripped off, when an image, faint, it is true, will be found beneath. This organic compound of silver is little affected by the short fixing that collodio-chloride prints now usually get. In the earlier days of the process the sulphocyanide-gold toning bath was exclusively employed. Now the prints are very frequently partially toned in a gold bath, and then finished in a platinum one. We have frequently been asked by correspondents the reason why prints so toned break out in spots a few weeks, even days, after they are finished. Now the platinum bath is used in an acid condition, and it stands to reason that if the prints are transferred to the fixing bath, without the whole of the acid being washed out, the hypo in the print will be decomposed, and sulphur compounds formed. With these facts before us, it is not surprising that some collodio-chloride prints do show signs of deterioration in the course of time. That, however, is not due to the process itself, but must be charged to the perfunctory way in which it is sometimes worked.

AN error occurred last week in the address of the Tress Co., when mentioning this firm's copying accessory. The correct address is 33, not 23, Oxford Street, W.

MOUNTING Large Bromides.—A suggestion is made in the "Bro-mide Monthly" for those who enlarge considerably, that it will be found to be an advantage to mount the picture on a stretcher, instead of on a board of the weight which the large size demands. The lightness thus obtained is equally a boon in hanging the picture or sending it on its travels round the exhibitions. The print is thoroughly damped at the back, pasted firmly to the frame, and allowed to dry slowly, when it will be found stretched as tight and even as the proverbial drum.

THE pronouncements of M. Auguste Rodin, the famous sculptor, in a recent communication to the "Express," should be taken to heart by all pictorial photographers who are apt to decry the beauties of their own country. Mr. Rodin says:—Here in England you have a land made for painters. Your atmospheric effects—in some ways akin to those of Holland—are infinitely finer and more varied than those you can find in the drier climes of Italy or France. In Italy and Southern France you may always count on your blue sky—gloriously beautiful and blue, it is true, but none the less hard and changeless; but here in England, especially in London, you have every day a sky as changeable and as beautifully coloured as one could desire. If, for example, you choose to spend the day on the Embankment by Chelsea, a locality greatly loved by Whistler, you can discern in the course of the day a change of sky and atmosphere and effect that is in itself a perfect drama. You begin with the red dawn, and before the morning hours are advanced there is a sky as black as night, and the rain descends in silver sheets. This may be followed by a serene and cloudless noontide that reminds one of the south. The afternoon draws on, and there follows a rich and mysterious sunset that precedes a blue-black, star-hung night. Then there are your fogs—fogs that Londoners rail at—yet if they be light they are a harvest of impressions to the artist. The Englishman has a habit of denouncing his old monuments and the statues in the streets of his city. They may not be very good, but, believe me, they are quite on a par with those of France and Germany. For some reason impossible to explain, sculpture has been in a state of decadence for the last hundred years, but this state of affairs should mend itself some day.

COLOURING LANTERN SLIDES WITH ANILINE DYES.

UNTIL recently, coloured lantern slides were invariably painted with oil or water-colour pigments, but the success of the three-colour process with stained films has again drawn attention to the use of aniline dyes as suitable materials for tinting transparencies. Hitherto the chief objection to anilines has been their fugitiveness, and this instability would undoubtedly be a serious drawback if it could not be prevented; but with improved chemical preparations such as are obtainable to-day, it is impossible to get a variety of colours that will stand the test of many years' use in a lantern without fading. I remember one particular scarlet which gave me trouble through its habit of changing to yellow. Thus, if I painted a lady's dress purple (red and blue) it would, after a few days, show up in bright green, or the same as if originally painted yellow and blue.

Another disadvantage, sometimes not noticeable until after the slide has been covered and bound, was fogging of the picture by crystallisation on the face of the film. Probably this might arise from the adulteration of the dye, though it might possibly be from a wash of too great strength. For a very small sum, however—about a shilling or one-and-sixpence—one may purchase a box of selected aniline colours free from the defects just pointed out, and these will yield soft and rich effects.

A Relief from Monotony.

The saying that "a lantern slide coloured is a lantern slide spoiled" is simply not true, for some of the most beautiful slides ever shown were painted by a Japanese artist. Moreover, colour gives more information than can be got from a plain slide, and also colour aids the perspective. What is more tiresome than a succession of slides with bare skies, and what more troublesome than printing clouds in from a separate negative to overcome the monotony? Yet with aniline dyes it is quite easy to put in either a simple graded sky or one with clouds in a few minutes. With oil or water-colours, on the contrary, the sky is the most difficult portion of the picture to obtain satisfactorily, at least by non-professionals, for most amateurs get it streaky or stippled.

Practical Maxims.

After trying both mediums I have some confidence in advising amateurs to try aniline colours, for the use of which the following few and simple directions may be of service:—

1. The slide to be coloured should be placed on a sheet of ground glass held in the opening of an ordinary retouching desk.
2. With a large brush charged with water and a drop of ox-gall, wash the film over the whole surface. This will remove any greasiness and prevent blisters which would otherwise occur if only a portion of the film be worked upon without previous wetting.

The film should now present a dull, moist surface without actual wet, and be capable of absorbing colour without any tendency to overrun the boundaries. See that no loose hairs from the brush are deposited.

3. Dilute the colour, if too strong, and get depth by repeated washes, except for small patches, which may be put on full strength, but no wash should be so dense as to clog details.

4. As a rule the density of the slide itself will yield the blacks, but occasionally; these may have to be assisted by colour. There is no satisfactory black amongst the aniline dyes, therefore, for branches of trees, black boots on figure studies, and similar small items, gum-water colour may be used with advantage.

5. If the slide be too pronounced in colour, soaking in water will remove the excess, though this should not be necessary with ordinary care.

6. Dissolve the powder colours in boiling water, not in cold water, and keep them in small bottles. About six or seven colours will be ample.

7. For fine details use a magnifying glass.

8. Test every slide in a lantern before showing it in public.

9. Work with two brushes, one charged with colour and the other moistened with water for softening the colour, or for absorbing and removing any colour that has been accidentally put in the wrong place.

10. Work quickly, and do not let drops of colour remain on the film before spreading where wanted.

WALTER BAGSHAW.

THE WEEK IN HISTORY.

The First Photo-Engraving.

IN point of obtaining finished though crude results, photo-engraving ante-dates photography proper by some ten years. Nicéphore Niépce, despairing of obtaining a proper representation by photography pure and simple, set himself the task of etching a metal plate on which he had deposited a "resist" by photographic means. And he succeeded to a passable degree in feebly etching metal plates by a primitive bitumen process, to which he gave the name of "héliographie." At what date he first obtained success cannot be definitely stated, but at any rate in the year 1826 he had copied by contact an engraving of the Cardinal d'Amboise. The engraving, still oiled as Niépce prepared it, to render it translucent, is now in the little museum at Châlon-sur-Saône, where is preserved a number of other Niépce relics. The process by which he made it is thus described in a letter from his son Isidore, written on March 10, 1867:—"I was a witness to the making of the portrait of the Cardinal d'Amboise. My father coated a tin plate with bitumen dissolved in Dippel's animal oil. He exposed this

to daylight behind the engraving, which he had rendered translucent. After a time he immersed the plate in a solvent in which the image gradually became visible. He then washed the plate, put it to dry, and afterwards etched it in acidulated water. The plate was afterwards sent by my father to M. Lemaitre, with the request that he would etch it more deeply. This was done, and Lemaitre took off a number of proofs, one of which he kept, sending the others, with the plate, to my father. I have given the last proof in my possession to my eldest son, and have sent to the museum at Châlon the plate itself, and other heliographic apparatus employed by my father."

The Coming of the Dry Plate.

JUST about three decades have passed since the great transition of photography from the wet plate to the gelatine emulsion was brought about. It is instructive to recall how the very rapidity of the gelatine dry plate fought against its general adoption. The worker who was wedded to collodion could not conceive of anything so sensitive even as the first dry plates,

and they, be it remembered, were little more rapid than a present-day lantern plate. So it came about that photographers would over-expose, and then complain of the thinness and flatness of the dry negatives. The difficulty was to get the wet-collodion worker to appreciate the altered conditions. Thus twenty-nine years ago to-day—in THE BRITISH JOURNAL OF PHOTOGRAPHY for March 10, 1876—we find the Rev. H. G. Palmer taking pains to point out the properties of the Kennett pellicle, the dried emulsion which was supplied at that time for the home preparation of plates. "As regards exposure," he writes, "it should be borne in mind that Kennett's rapid pellicle and plates are, with good light, really instantaneous. Nothing can surpass the cloud, wave, and street views taken with this preparation; and for babies' portraits it is simply perfection itself."

Sir John Herschel's Discovery of Photography.

In "The Week in History" for February 17 the paper of Talbot before the Royal Society in 1839 fell in its allotted place. He read it on February 21. On March 14 Sir John Herschel, knowing nothing of what Talbot had done, contributed a paper to the Royal Society. He also had heard of the discoveries of Daguerre, and, like the good chemist that he was, he promptly set to work and produced one or two photographic processes within the space of a month or so. In reading his "Note on the Art of Photography, or the Application of the Chemical Rays of Light to the Purposes of Pictorial Representation," Herschel exhibited twenty-three copies made from engravings, etc., by contact, and one taken through a lens.

Processes to Order.

"As an enigma to be solved," wrote Herschel, "a variety of processes at once presented themselves, of which the most promising are the following:—First, the so-called deoxydising power of the chemical rays in their action on recently precipitated chloride of silver; secondly, the instant and copious precipitation of a mixture of a solution of muriate of platina and lime-water by solar light, forming an insoluble compound, which might afterwards be blackened by a variety of agents; thirdly, the reduction of gold in contact with deoxydising agents; and fourthly, the decomposition of an argentine compound soluble in water, exposed to light in an atmosphere of peroxide of chlorine, either pure or diluted."

A Complete Process with Silver.

As reported in the "Abstracts," Herschel proceeded to develop only one of these methods. He "inquires into the methods by which the blackened traces (of silver chloride) can be preserved, which may be effected, he observes, by the application of any liquid capable of dissolving and washing off the unchanged chloride, but of leaving the reduced, or oxide of silver untouched. These conditions are best fulfilled by the liquid hyposulphites." In thus originating a practical photographic process, Sir John Herschel was returning to his first scientific love, viz., chemistry. Twenty years before, when he was a young man of twenty-two, he had a narrow escape from choosing chemistry as the sphere for his versatile genius. But he was led to astronomy and physics, and completed the gigantic labours of his father in sidereal astronomy. Almost the only chemical investigation which he prosecuted in those early days recurred to the advantage of his photographic researches.

Fixing with Hypo—Herschel's Work in 1819.

In the "Edinburgh Philosophical Journal" for 1819 appears a paper by Herschel, "On the Hyposulphurous Acid and its Compounds." In it is described the solvent action of hyposulphites on silver chloride, bromide, and iodide. Herschel was the first to observe this fact, and he examined the properties of the solutions very thoroughly, for he specifies the various hyposulphites of silver, and points out the unstable character of those which are formed in presence of an excess of silver salt. The proper chemical conditions for perfect fixation were thus recognised twenty years before photography came into existence, and Herschel likewise devised the delicate silver nitrate test for hyposulphite which is still the most reliable method of detecting traces of the fixing salt in the wash water. The method, according to Herschel, is sensitive enough to detect one part of hyposulphite in 97,800 parts of water. Herschel even does not omit a mention of the curious sweetness of a solution of silver chloride in hypo; the intensely metallic taste of the fixing bath disappears as it accumulates silver, and many of us in the old days were accustomed to make that a rough-and-ready test for the exhaustion of a fixing bath.

Collodio-Chloride Paper.

March 16 is the fortieth birthday of the printing process which of late years has firmly established itself in the affections of the British photographer. Not that it is now offered him in the same shape as that in which it was demonstrated to the Royal Photographic Society by G. Wharton Simpson in 1865. Far from it; but on this occasion the employment of collodion as the vehicle for silver chloride in positive printing was first advocated and shown to be a practicable method. Simpson's emulsion was made from about one and a half grains of chloride of calcium and seven and a half grains of silver nitrate per ounce of collodion, and he showed that toning in one or other of the gold baths gave him every shade of tone from sepia to black. And he advanced certain reasons for the greater permanency of the process, which may still be said to hold good. "There is no insoluble silver compound formed like that formed with albumen. A properly fixed and washed print by this process, when tested with hydrosulphuret of ammonia, gives no indication of the presence of silver in the whites as an albuminised print does."

Twenty-five Years of Platinotype.

On Wednesday next, March 15, precisely twenty-five years will have elapsed since Mr. Willis applied for the third patent in "photo-chemical printing." The progress of platinotype from the time of its first patenting in 1873 has been towards simplicity. The first formulæ and directions would repel the go-as-you-please worker who has found, to his astonishment usually, that platinum is the simplest of all processes. The sensitising solutions and the after manipulations which they involved were not free from the reproach of hypo and other debatable substances, but in the patent of 1880 the process was raised to a height of chemical purity by the claim of only two salts in the sensitiser—the sensitive iron compound, usually ferric-oxalate, and platinum in the form of potassium chloroplatinate.

The same patent claims the use of various salts, citrates, phosphates, and others as developers, and prescribes the employment of the developer, hot, warm, or cold.

HISTORICUS.

FAMOUS RESIDENCES IN ST. PANCRAS.—At the forthcoming meeting of the St. Pancras Borough Council, a proposal will be made to photograph the former residences within the area governed by that authority of the following celebrated inhabitants:—John Leech, 32, Brunswick Square; Charles Dickens, 48, Doughty Street; George

Cruikshank, 263, Hampstead Road; John Ruskin, 54, Hunter Street; Thomas Carlyle, Ampton Street, Gray's Inn Road; John Constable, 76, Charlotte Street, Fitzroy Square; Sydney Smith, 14, Doughty Street; and the Marquess of Salisbury, Fitzroy Square, W.

ORTHOCHROMATIC PHOTOGRAPHY.

II.

The Position of the Filter.

THERE are three practical positions in which the filter may be placed: either immediately in front of, or behind the lens, or in front of the plate. And in regard to these positions we have to consider the speed of the filter (or efficiency of light transmission), the effects of want of homogeneity or flatness, and the effects of aberrations naturally introduced by the filter, considered as a plate of refracting material. I have seen various opinions upon the first point, but it appears to me that if the geometrical law of absorption holds good with moderate variation of light intensity, then the filter will transmit a definite proportion of each wave length of the incident light, the consequence being that the speed efficiency of a filter is independent of its position. I have found that this is confirmed by experiment. The effect of any non-homogeneity in the filter, or any want of flatness, is to alter slightly the direction of the light passing that part, and the effects will therefore be the more marked the further the light has to travel to the plate after passing the filter. So that inferior glass may be used if the filter is placed close to the plate, but it must then be free from air-bubbles and other visible flaws.

The Filter and Focussing.

When a filter is introduced anywhere between the lens and the image it throws the image back by a distance equal to $t\left(\frac{\mu-1}{\mu}\right)$ where t and μ are the thickness and refractive index respectively. For this reason when the filter is used behind the lens the focussing must always be done through it.

If it is placed in front of the lens, then it is as if the object were moved away by the amount indicated above, so that for all ordinary work where the object being photographed is some distance away, it does not affect the focus. In this case the light enters the filter parallel and emerges in the same condition, so that the camera can be focussed and the filter placed on the lens afterwards, which is a great convenience. Moreover, this position of the filter is one which requires the least alteration in adapting a camera to work with filters, and is perhaps the best for small cameras. When the object is near the camera, as in copying, then again it is necessary to focus through the filter.

Aberrations Caused by the Filter.

There is in addition to this change in position of the image or apparent position of the object, a distinct introduction of aberration. Light proceeding from a point in any refracting medium does not, on emergence into the air, appear to proceed from one point only. You know that if you look vertically down through water to the bottom, the bottom appears to be raised somewhat. If, however, still looking at the same point, you walk away the bottom appears to rise until it looks to be only just below the surface. This follows directly from the *sine* law of refraction.

It is the converse case which is of importance in filter work, viz., that in which a set of rays (normals to a wave surface) start to converge to a point in the image plane, and then owing to the refraction through the filter, fail to do so when the angle included by the extreme rays is great.

The light on the margin of the cone would reach its focus a little in front of the axial light, but as the angle of the cone of light used in photographic work is almost always small, any direct effects of this are rarely seen in practice. But there is a secondary effect which might show itself in wide angle work, that is that the light proceeding to the edge of the plate, would, owing to its obliquity, be caused to come to a focus in front of the image plane of the central light, thus causing a curvature of field concave to the lens. As the refraction index varies with the wave length, each colour would form a separate saucer-shaped image surface of a different size from the

others, but all nearly touching at the axis. Trouble due to these effects may be avoided by not having the filters too thick.

Holding the Filter.

Of devices for holding the filter in front of the lens, there are two which I have found useful. One was described in a photographic journal some little time ago, and consists of a rubber band stretched double along one face and looped over the opposite corners. The parallel pieces may be stretched over the hood of the lens. The other has, I believe, been described by Mr. Anthony. It consists of a square piece of flat metal, with a circular hole and flange to fit on the lens hood. Two edges of the square are folded over to just grip the filter. This holder is placed on the lens hood with a diagonal vertical, and the turned up edges below. Any square filter of almost any size can readily be slipped into it.

A Few Illustrative Cases.

Clouds.—For clouds, especially if they are thin ones, it is generally desirable to obtain a fair contrast between the white cloud and the blue sky. Now while a white cloud reflects light of all colours equally, the upper regions of the air reflect the shorter wave lengths in greater quantity than the long ones, so that the light from the sky is deficient in green, and still more deficient in red. As noted above, a filter of the second type cutting out the ultra-violet, violet, and blue, brings out the clouds more prominently than the ordinary plate, and if the greatest contrast were required it would be obtained by the use of a red screen and panchromatic plate.

Portraiture.—The defects of the ordinary plate in portrait work consist chiefly of a darkening of any freckles, which are generally yellow or orange in hue, and therefore do not reflect as much blue as the rest of the skin. A yellow filter of the tartrazine type will reduce this contrast, and an orange or red filter with a suitable plate will give a still more pleasing result, though this may entail too long an exposure.

Yellow Stains.—The case of copying a picture with yellow stains is similar to the last. The effect of the stain can be partially, or sometimes totally, removed in the new negative by the use of a red filter.

Photographing Copying Ink.—In order to get sufficient contrast in photographing a violet copying ink, which reflects violet, blue, and red light, a combination of filter and plate recording the green only should be employed. A green sensitive plate in combination with a strong tartrazine filter will do this.

The light blue ink sometimes seen on circulars is best rendered by a red filter and red sensitive plate.

Dark Red Woods.—Sections of dark red woods such as cocobolo and snakewood require a red filter and red sensitive plate to give the best record of the detail of the markings.

Interference Fringes.—For photographing the various interference fringes, such as Newton's rings, which occur in optical work, it is best to use a monochromatic light, especially if measurements have to be made from the negative. Monochromatic light of various wave lengths may be obtained by the use of selective filters in conjunction with a luminant giving a line spectrum such as a mercury lamp. Certain somewhat deep filters may be constructed which transmit only narrow regions of light. Where they can be used they are more convenient than the above. For instance, Mr. W. Bennett in his work on skew refraction through lenses has used a filter containing acid green, 2.5 mgs., and tartrazine 0.05 mgs. per c.c., in conjunction with an erythrosin plate. The light here recorded extends from λ 4,900 to λ 5,100.

Absorption and Line Spectra.—To photograph spectra one requires a plate recording the most extended range of wave-lengths and a filter to render the record as even as possible with the particular spectrum being used.

A. J. BULL.

THE CAPACITY OF DIFFERENT PRINTING PROCESSES FOR RENDERING GRADATION.

I.

[A Paper read before the Glasgow and West of Scotland Amateur Photographic Association.]

WHEN one considers the enormous amount of literature bearing upon photographic subjects which has been poured forth in ever-increasing volume for so many years, it seems almost hopeless to find anything that has not already been fully dealt with and discussed. Nevertheless I cannot recall any systematic attempt to compare the characteristics of the different printing processes in general use, and I am about to show you the results of a number of experiments which may bring the matter before you in a new way, though the subject may not be new. It is, of course, common knowledge that different printing processes give different results from a given negative, but the object of my paper is to show the character and extent of the difference, and, if possible, to indicate what kind of negative is best suited to each process.

The Relationship of Gradations.

At the outset the investigation seemed a comparatively simple matter. It was only necessary to prepare a negative having a series of gradations bearing a known relation to each other, and from that to make prints, carrying the exposure to such a point that the deepest shadow gradations merged into a uniform depth, showing that the limit of the process had been reached. The relationship of the gradations, however, presented unexpected difficulties. The most obvious plan was to adopt the Hurter and Driffield method of exposing a plate in strips for periods in geometrical progression, thus on development securing gradations in corresponding ratio.

Experiment proved, however, that in a sufficiently long scale for my purpose there would probably be portions of under-exposure and over-exposure at the respective ends of the scale, and it did not seem to me possible that anyone inexperienced in photometrical work could measure these opacities with any degree of accuracy. The next idea that presented itself was to superpose strips of uniformly fogged film, but celluloid film was obviously out of the question, as the colour and opacity of the celluloid would certainly falsify the resulting scale. Gelatine film alone seemed more hopeful, and after several failures to develop a large area of that very "wobbly" material to uniform opacity, a successful batch was obtained, only to find that the resulting graduated screen was useless, as a very few thicknesses of the apparently colourless gelatine had sufficient opacity to vitiate the results.

Making a Graduated Screen.

Although this screen proved useless for my purpose, it furnishes a most instructive lesson on the importance of stopping development at the right moment. You will notice that, although the film is so lightly fogged, successive thicknesses of it quickly build up a great degree of opacity, and, by adding or subtracting the single thickness which you will find loose, you can see the great effect the addition of even such a slight amount of silver has in increasing the opacities of the different steps of gradation; in other words, its effect on what we are accustomed to call the "density" of the negative.

Having failed to get what I wanted by purely photographic methods, I tried numerous experiments with other materials, and finally found a pure white tracing paper which gave a long and useful scale of gradations when superposed in successive thicknesses. The gradations are so proportioned that the opacity is about doubled at every second step, but unfortunately there is a very slight departure from that simple rule which would cause the higher opacities to be overestimated. It was necessary, therefore, after finding the range of opacities which would actually come into use in my experiments, to measure their value by actual tests for each one. The method was simple but somewhat tedious.

Use of the Graduated Screen.

Using a certain make of bromide paper, a two-grain amidol developer, and a distance from a gas flame (full on) which would give a decided tint to the smallest opacity after five seconds' exposure, such an exposure was given to a small piece cut from a sheet of the paper. That was removed, and the rest of the sheet exposed behind the screen for a time estimated to be correct for some other opacity. The whole being developed together, if gradation No. 1 which had received five seconds' exposure appeared together with gradation No. So-and-so which had received the longer exposure, and if both ultimately reached the same tint when development ceased, it was reasonable to conclude that they had received the same amount of light. Thus gradation No. 1 with five seconds gave the same tint as gradation No. 15 with 320 seconds, therefore their relative opacities are as 1 to 64.

Having tabulated these opacities, it only remained to print as many different kinds of papers behind the screen as I could obtain, and to compare the results both as to the number of gradations rendered by each and as to the character of the gradations.

For testing printing-out papers several screens were required, and having made a number, four were selected for use which proved to be exactly similar in time of printing. For development papers one screen only was used throughout, and whenever comparative tests were made screens cut from the same sheet of paper were used.

I have dealt at some length with these screens because the whole value of my experiments turns on the correctness or otherwise of the means of investigation; also because it seems to me that similar screens should be of frequent use to photographers, not only for testing papers, but for making comparative speed tests of plates, testing plates for halation, latitude of exposure, etc., also for use as actinometers in printing.

Testing Plates.

Having secured the means of testing the papers, I turned my attention to plates, as it seemed desirable to find what gradation a plate is capable of giving. Several popular brands were chosen and exposed behind one of the graduated screens. A four-grain amidol developer was used, and development was prolonged till the denser parts were completely through to the back and all developing action seemed to have ceased.

Very striking differences were found between different makes of plates. In some, quite a number of the most exposed divisions of the scale had run up against the glass, so to speak, and were equal in opacity, while in some cases signs of reversal could be seen when the exposure was sufficient to bring out nearly the highest opacities of the scale. In other cases nearly the whole scale was clearly rendered, one plate in particular giving the entire scale clearly, without halation. Of course, all the plates were backed.

As the opacity of the gradations on these plates could only be ascertained by direct experiment, tests were made on the same principle as the tests of the screens, and the range of opacities was found to range from 1 to about 700 in average plates, and 1 to over 1,000 in the best, and these opacities are due to silver alone, no developer stain being present. In these figures I take as 1 the faintest deposit that has any printing value. Clear glass may be disregarded, as I do not think any really good negative has any quite clear glass.

WILLIAM GOODWIN!

[The remaining portion of this paper will appear next week.—Eds., B.J.P.]

SOME PROBLEMS IN SHUTTER DESIGN.

III.

COMPACTNESS is one of the essentials of the modern shutter, and when extension springs are used it becomes necessary to arrange them alongside one another, or in any available spaces, using the number of cranks and levers and other members familiar in the ordinary shutter. But compression springs make possible the simple arrangement of parts for actuating the shutter, shown in Fig. 9. The tube *a* having a slot *b* along it contains the push button *c* whose wing *d* projects through the slot in the tube. A spring *e* thrusting against the fixed stop *f* serves to return the push button after it has been pressed.

The Control of Automatic Exposures.

The pieces *g* and *h*, which slide freely within the tube, have pins projecting through the slot *b* and engaging with the piece *i*, which is called a gate, because its business is to permit or prevent, as required, the passage of the pins and their sliders, *h* and *g*. The gate is pivoted on the axis *xy*. Between the sliders *g* and *h* is the mainspring *j*, which is compressed through the medium of the pin of *g* and the wing *d* when the button *c* is pressed. As this is being done, the slider *h* tries to go forward, but is obstructed by the stop on the gate. The face of this stop is sloped so that the tendency is to depress the gate, but this is prevented because the pin of *g* is yet beneath the part *k* of the gate. When, however, the pin of *g* has been pushed just beyond the part *k*—that is, when the mainspring is fully set—the gate falls, the part *k* obstructs the return of the slider *g*, the slider *h* shoots forward and opens the shutter to which it is connected, and at the same time compresses the spring *m*, whose duty it is presently to close the shutter by returning the sliders to their normal position.

This occurs when the gate is moved so that the part *k* no longer obstructs the return of the slider *g*.

Hand Exposures.

In the case of exposures whose duration is determined by hand, the gate is moved for this purpose by a second motion of the push button *c*, and to terminate exposures automatically the gate is moved

Fig. 9.

by the operation of a spring, set in action by the opening of the shutter delayed in its action by the variable obstruction of the pneumatic piston, and which finally moves the gate and permits the shutter to close. By this arrangement, among other things, the important principle already laid down has been observed, and the impact of the moving part has been taken away from the pneumatic piston. Moreover, the spring which operates the piston, having no other function, can be made adjustable as to strength, so that the longest time to be controlled—the second—can be accurately adjusted, and the very shortest time to be controlled may be

adjusted by means of a screw whose point at the required time actuates the gate. With the extreme time intervals thus adjustable

Fig. 10.

the intermediate times, which depend upon the shape of a fixed cam, are included in the adjustment and made correct.

Variable Motion of Mechanism from Fixed Diaphragm

In every diaphragmatic shutter, that is, one of which the full aperture may be varied at will, the problem has to be met of getting from the motor mechanism, whose motion is constant in amount, a variable motion of the diaphragm. Fig. 10 shows a simple solution of this problem. At *a*, three links are shown pivoted together at 1. The end 2 of the middle link is pivoted to some fixed part of the instrument. Now if motion be imparted to link end 3, so as to move it up to the position shown at *b*, through the distance 4 the other

FOREIGN NOTES AND NEWS.

The Instability of Uranium-Toned Prints.

M. LEMAIRE read a paper before the Société Française de Photographie at the commencement of this year on the cause of the instability of uranium-toned prints, and pointed out that the image was composed of a mixture of the ferro-cyanides of uranium and silver, and that if the toned print was immersed for five minutes in a 0.2 per cent. solution of carbonate of soda, it showed no trace of the characteristic iridescence after six months' exposure to the air, and only faint traces after ten months. Comparative tests were made, and the author comes to the conclusion that the alteration of the prints is entirely due to the silver ferrocyanide, and that the treatment with sodium carbonate converts this into the more stable carbonate of silver, and that this may be eliminated by subsequent treatment with a 5 per cent. solution of nitric acid, and the prints are then stable.

Printing without Light.

Niewenglowski has found that it is possible to reproduce a negative or positive without the action of light, if the image is deeply toned with uranium. He suggests that the image should be first bleached with a 2 per cent. solution of potassium ferricyanide, then washed for about one and a half hours, and then deeply toned in—

Water	30 ccs.
Uranium nitrate	2.5 g.
Hydrochloric acid	5 drops.

The image must now be washed in acidulated water, rinsed in pure water, and then immersed in a bath of—

Water	30 ccs.
Hypo	1.5 g.
Sodium bisulphite	0.7

and then washed and dried. It is necessary that the whites should be pure. This toned image placed in contact with an unexposed plate gives, in two days or longer, a perfect reproduction. Whilst of little practical value, the process is probably another interesting application of the radio-activity of uranium.

Some New Sensitisers.

In the current number of the "Zeitschrift für Wissenschaftliche Photographie," Herr Kieser gives the results of some experiments with some new dyes, which were made by Dr. König in a similar manner to the now well-known isocyanines. Various strengths of dye solutions were used, with and without ammonia, and the plates were tested in a diffraction-grating camera and exposures of 5, 10, 15, 30, 60, and 120 seconds given. The mother-plate showed, with an exposure of 30 seconds, a density of 2.5, and this was measured with a polarisation photometer for every 100 Angström units in the spectrogram, and then the curve plotted out. The bathed plates were also measured for the 30 seconds' exposure, and all developed with an edinol developer. The results prove whether the dyes are practical sensitisers, and does not show when they are very faint sensitisers.

1. Dye from Bromocyanpyridine and Aniline.—Readily soluble in alcohol giving brown solution; soluble with difficulty in water with brownish-yellow colour. Concentration of bath, 1:25,000. Blue sensitiveness lowered. Maximum sensitiveness at λ 530, extends to λ 592. Slight minimum at λ 500; increase of dye fills up this minimum, but general sensitiveness considerably depressed; weaker solutions give weaker sensitising, but a distinct narrow band at λ 680. Slight fog caused. Ammonia entirely destroys sensitising action.

2. Dye from Bromocyanpyridine and Monomethyl-aniline.—Readily soluble in water, citron-yellow solution. Blue sensitiveness slightly depressed. Dye strength, 1:25,000. Sensitises to λ 560, slight maximum at λ 525; briefer exposures showed slight minimum about λ 500. No fog. Stronger solutions strongly depress general sensitiveness; minimum strongly marked, due obviously to screening action of the stained gelatine. Ammonia nullifies sensitising property. This dye is a good blue-green and green sensitiser; similar, but inferior, to acridine orange.

3. Dye from Bromocyanpyridine and p-Amidophenol.—Aqueous solution reddish brown. Dye strength, 1:25,000. Maximum sensitiveness to λ 570; minimum, λ 490- λ 550. Blue sensitiveness strongly depressed. Slight fog. Ammonia destroys sensitising property.

4. Dye from Bromocyanpyridine and Sulphanilic Acid.—The sodium salt is readily soluble in water, almost insoluble in alcohol; the reddish-yellow solution shows yellow fluorescence, but no sensitising action with or without ammonia.

5. Dye from Chlorocyanpyridine and o-Toluidine.—Readily soluble in water, giving brownish-yellow solution, with yellow fluorescence. Dye strength, 1:25,000. Blue sensitiveness lowered, distinct fog. Sensitiveness equal up to λ 560; indistinct maximum, λ 540. Ammonia destroys sensitiveness.

6. Dye from Bromocyanpyridine and β -Naphthylamine.—Easily soluble in alcohol, with difficulty in water, giving brownish-yellow solution. Blue sensitiveness considerably depressed. Sensitises like No. 5, but rather stronger, and reaches λ 600. The density in the maximum is, as compared to the blue, as 0.2:1. Ammonia destroys sensitising action.

7. Dye from Bromocyanpyridine and α -Naphthylamine.

8. Dye from Bromocyanpyridine and Amido-azobenzol.—These have no sensitising action.

9. Dye from Bromocyanpyridine and Benzidine.—Easily soluble in water. Blue sensitiveness only slightly depressed; very slight fog. Sensitises continuously to λ 620, but less strongly than No. 6. Stronger baths than 1:25,000 produce screening action. Ammonia acts unfavourably.

10. Dye from Bromocyanpyridine and p-Phenetidine.—Slightly soluble in water. Strength, 1:25,000. Sensitises continuously from blue to λ 630, with good intensity, with exposure of 120 seconds; extends to λ 700, faint, scarcely noticeable. Minimum, λ 510; greatest density, λ 560- λ 580. Blue sensitiveness strongly depressed. Ammonia useless. The action corresponds to that of the isocyanines, but the latter do not lower the general sensitiveness so much.

11. Dye from Bromocyanpyridine and o-Anisidine.—Somewhat similar to No. 6, but weaker; no fog. Ammonia useless.

12. Dye from Bromocyanpyridine and p-Amidodimethyl Aniline.—Easily soluble in water. Destroys sensitiveness and produces fog; no sensitising action.

With all these dyes it is interesting to note that the maximum of sensitiveness is shifted from the place of maximum of absorption by no less than 1,000 Angström's units, whilst with the cyanines it is only 300, and with the eosines 400 units. All the dyes are light sensitive, and although no connection could be traced between the light sensitiveness and sensitising power, it is interesting to note that three out of the four dyes which do not sensitise are the least sensitive to light. So far plates bathed with the dyes have kept as well as eosine bathed plates.

Photo-Mechanical Notes.

A Soap Economiser.

In the etching room, and indeed many departments of the process-house, there is a great need for soap, and this is in consequence often wasted. One of the most ingenious means of economising in this respect consist of the provision of a box about 9 by 6 in. and 6 in. deep, pierced at either end with a hole about an inch from the bottom, this hole being circular and a little larger than a piece of broom-handle, 16 in. long,

which is passed through the box, and has a screen put in it in the middle to prevent it being pulled right out of the box.

The box is now filled with soft soap, and closed and locked. In order now to get the soap, the broom-handle is pushed, and the half that was in the box comes out on the other side covered with soap, which the man washing puts on his hands. If more is required, the handle is pushed in again, and the other end comes out covered with soap.

Colour-printing from Aluminium.

The following process is intended for the production of sets of aluminium plates from which to print a coloured version of a photographic original. It is patented by Charles Harrap Shirley, Canonbie Road, Forest Hill, London, and J. Crawford, 43, Carden Road, Peckham Rye, London, who in specification No. 4,345, 1904, explain their *modus operandi*. From a negative of the object to be reproduced in colours, a positive is made on flexible or light rigid film, and from this transfers are made with greasy ink direct upon aluminium by contact and under pressure in any lithographic or typographic press. Such transfers are then selected for the various colours of the picture, and those portions which are required for printing purposes may be covered by a nitric acid resist as employed in the well-known methods of lithography, as dusts or in solutions, of the nature of silica, sulphur, talc, other non-metallic resists, used in dust form or semi-liquid aqueous mixture, as well as organic resists: for example lacs, used as spirit varnishes, and metal mixtures such as aluminium bronze dust, used as, a dust or semi-liquid aqueous mixture, with such non-metallic and organic resists. When so covered, that portion of the work not required as a printing surface may be removed by such corrosive bodies as sulphuric acid, caustic soda, caustic potash, creasote and its derivatives, oxalic acid and its acid compounds, or other suitable solvent, used in weak solutions of no fixed proportions, or by a special pencil composed by mixing any of these bodies as dry powders or solutions with a suitable chalk, clay, or plaster and water in no fixed proportions.

Klimsch's Jahrbuch.

Messrs. Klimsch and Co., of Frankfort-on-Main, have themselves established such a high standard in the technical production of their yearly review of printing and "process" matters that the task of equalling their previous records is no slight one. We expect to find them not only inculcating methods in the literary pages, but demonstrating, in their own work, the arts of the engraver, printer, and binder. The present "Jahrbuch" is bound between covers made

to imitate a metal plaque, mounted on marble, and cleverly though the work is done the result is disappointing. The publishers may well find fault with their art advisers in permitting them to simulate materials which seem to us quite out of place as book covers. We cannot extend our strictures to the contents, which is a model of beautiful printing, and includes a number of supplements illustrating current reproduction processes. Among these a specimen of half-tone with the Klimsch grain screen is notable as a piece of work in which the "wooliness" of much grain work is largely avoided. Some striking work is shown in illustration of photo-mechanical methods in the printing of wall papers and the like, but perhaps the most important plate, in the eyes of the photo-engraver, is that made with the Schumacher vignette stop and etched in forty seconds with the new Holmström machine, to which two novelties we refer further in the next paragraphs. The text pages include articles by leading German authorities on half-tone, colotype, photogravure, and three-colour matters. The "Jahrbuch," which ranks with "Penrose's Annual" as an ocular demonstration of present day reproduction practice, is obtainable from Messrs. Hunter's, Ltd., Poppin's Court, Fleet Street, London, E.C., price 6s.

Etching by Machine—The Holmstrom Method.

Although the "acid-blast" etching of Levy has been talked about now and then since it was first demonstrated in the Paris Exposition of 1900 nothing has been seen of the installation on the market. A Swedish inventor has now perfected a machine whereby extremely rapid etching with a comparatively weak acid is obtained in a different way. Levy sprayed the acid at high pressure over the plate. By the new method the acid is hurled against the plate by two discs, rapidly rotating in opposite directions. Messrs. Klimsch and Co., who are placing the apparatus on the market, claim for it that zinc half-tones are completely etched in 40 seconds with a 6 per cent. acid. It is found that a kind of automatic fine etching takes place, in consequence of the more rapid etching of the lights in comparison with the closed shadows. In this way good printing depth and brilliant lights are obtained without local varnishing of the plate and without fear of "greying" the shadows; under-cut was conspicuously absent.

In etching line work on zinc, a short etch in a dish is given after the plate has been etched in the first place and inked up wet. It is then again inked up and dusted, and transferred to the machine, in which the etching liquid is 25 per cent. nitric acid. According to the proportion of white ground in the drawing, etching is done for from eight to fifteen minutes. Dragon's blood is then dusted over and melted—this occupies only a minute or two—and a short final etch completes the process. The time occupied from first to last is not more than 1½ to 1½ hours.

The Schumacher Vignette Stop.

A new form of stop for half-tone work has been designed in the Klimsch laboratories by Herr Otto Mente and Dr. P. Schumacher, with the object of obtaining a design of aperture which would permit of the same stop being employed for different degrees of reduction. The form of the new aperture is circular, with radial slits projecting from it. The diameter of the open central circle is considerably smaller than that of a stop as usually employed, and the slits, which provide a certain vignetting action, extend within a circle corresponding in diameter with that of the customary stop. A set of three stops of this form is stated to be equal to all the ordinary requirements of half-tone reproduction. The dot formation is found to be equal to that by the usual methods, but the exposure can be cut down to half or three-quarters the usual time.

As mentioned in "Ex Cathedra," the exhibition of process engraving at South Kensington will at last open, about the middle of the present month.

Exhibitions.

NORTHAMPTON.

THE exhibition of photographs promoted by the Northampton Museum Committee and the Photographic Section of the Northamptonshire Natural History Society was opened on Friday last by the Mayor of Northampton (Councillor A. E. Marlow), at Upper Assembly Room, Town Hall, Northampton. The great feature of the exhibition is the really fine loan collection by some of the leading British and French exponents of camera craft. Among the British work on view are representative pictures by Alexander Keighley, A. Horsley Hinton, Charles Moss, W. Thomas, F. J. Mortimer, Charles Job, David Blount, Fred Hollyer, Reginald Craigie, J. Craig Annan, Harold Baker, Viscount Maitland, Mrs. G. A. Barton, Mrs. A. O. Jennings, J. C. Warburg, Charles F. Grindrod, F. H. Evans, F. Sutcliffe, S. M. Whitehead, Walter Bennington, and S. Page Croft. The French School is well represented by M. Demachy, Major Puyo, G. Grimpel, M. Bucquet, A. Hachette, M. G. Ecalle, and Leline Laguarde.

The Royal Photographic Society lend a collection of a dozen or more of Rejlander's photographs.

Though the competitive exhibits are hardly of the high standing of the loan collection, they make a fine display. The local classes met with extremely encouraging entries, and though in the landscape class the prizes go to Wellingborough and Kettering, Northampton is well represented. The judges were Mr. A. Horsley Hinton, Mr. Alexander Keighley, and Mr. Andrew Pringle. Their awards were:—

OPEN CLASSES.

Landscape.—Silver medal, J. E. Latham, South Manchester ("Eventide"); bronze medals, G. Renwick, Burton-on-Trent ("The Imprisoned River Grows Below"); W. Clayden, Plymouth ("A Gleam of Light"); and Arthur Marshall, Nottingham ("Shadows").

Portrait and Figure Studies.—Silver medal, A. E. Coleman, Stonehouse, Devon ("The Dinner Hour—A Quiet Game of Nap"); bronze medal, C. L. Brailard, Redlands, Cliftonville, Northampton ("A Study").

Architecture.—Silver medal, W. A. Clarke, Moseley "South Choir Aisle, Ely"). Mr. Clarke's carbon architectural studies are quite the feature of the class. The judges, in fact, considered that the other work in the class was hardly good enough by comparison to receive the bronze medal.

Lantern Slides.—Silver medals, W. Farren, Cambridge ("A Reed Warbler"), and Rev. H. W. Dick, Miles Platting ("The Town Cobbler"); bronze medal, H. Wormleighton, Leicester.

LOCAL CLASSES.

Landscape, Seascape, etc.—Silver medal, Miss J. F. Dulley, The Lindens, Wellingborough ("Wave Study"); bronze medal, H. Evans, Market Place, Kettering ("Thorpe Malsor Lane").

Portrait and Figure Studies.—Silver medal, Dr. W. Ross, 87, St. Giles' Street, Northampton ("A Study"); bronze medal, C. L. Brailard, Northampton.

Architecture.—Silver medal, E. J. H. Felce, Adams Avenue, Northampton ("Light and Shade—A Crypt Study"); bronze medal, E. G. Holt, Ivy Road, Northampton ("The Triforium, Gloucester"). Both these exhibits are highly creditable to the competitors. Mr. Felce, who is a specialist in architectural work, well deserved the silver medal. Mr. Holt's work, too, is excellent, and there are others in the class whose work is not very far behind either.

Hand Camera Work.—Silver medal, T. W. Milner, Canal House, Blisworth ("Breaking the Ice"); bronze medal, W. J. Bassett Lowke, Kingswell Street, Northampton ("The Morning Plunge").

Lantern Slides.—Silver medal, E. J. H. Felce, Northampton ("Hoar Frost"); bronze medal, H. Manfield, Moulton Grange, Northampton ("Winter Scene").

CHAMPIONSHIP CLASS.

Medal presented by the "Amateur Photographer" for the best picture in the competitive classes, to A. E. Coleman ("The Dinner Hour—A Quiet Game of Nap").

BRECHIN EXHIBITION.

LAST week the Brechin Society showed evidence of its continued vitality in an exhibition of members' work in the Corona Hall, Brechin. The committee had the valued assistance of Mr. David Waterson, A.R.E., in the decoration of the hall. Twenty-five members contributed 177 prints. Members who had gained medals in other fields did not show their pictures for competition, but for exhibition only; but new work showed that the ability of the members was by no means exhausted. Mr. John B. MacLachan, Secretary of the Scottish Photographic Federation, officiated as judge. J. C. Robertson gained two medals with "The Pine Tree," a tall gnarled pine on a hilltop with a glimpse of the country beyond, and "A Study in Architecture," a panel picture showing a little girl seated on the floor with building bricks, the background being a lace-curtained window—an effective and striking arrangement. D. M. Watt is medalled with "A Riverside Path" (21), a convincing woodland study, showing good perspective. W. Lamont is another double-barrelled medallist with "The Flauchter Spade," a convincing character study; and "In Winter's Shroud" (73), a realistic rendering of winter, beautifully simple. John Kirk, who had so much to do with Brechin's last exhibition, is medalled for a delicately limned picture, "A Pastoral" (41). In this class "honourable mention" is awarded to J. D. Ross (2), Arthur Boulton, John M. Dunn, R. C. Dalgity. Class II.—Miss L. S. Duke gains the medal here with a delightfully soft copy of a painting (157). Class III (professional).—The medal in this class is awarded to "Meditation" (175), a figure study, by James Silver.

SOUTH LONDON PHOTOGRAPHIC SOCIETY.

THE sixteen annual exhibition of this society was opened on Saturday last at the Camberwell Baths by the Mayor of Camberwell. The exhibition is again up to the high standard usually associated with the name of this society, and the number of entries show a slight increase on last year's exhibits. The large bath, suitably floored over, makes an admirable room for an exhibition of this kind, and the pictures, tastefully hung in panels on draped screens extending right round the building, are shown to the best advantage. The trade stalls, which occupy the centre of the floor space, are not quite so numerous as in previous years, owing doubtless to the recent depression in trade, but the attendance has proved well up to the average.

The judges, Messrs. J. T. Ashby and H. W. Bennett, made nine awards in the open classes and nine in the members' classes—the latter containing no less than 230 entries, and all remarkably good work. The remaining 292 exhibits are in the open classes. In Class H (open), Portraiture, the first award (silver plaque) goes to Miss M. Y. Prentice for "Study of a Head" (293), a technically good portrait of an old man, but very harshly lit. The bronze plaque is awarded to J. Hepburn for an excellent little cottage interior entitled "Cantie wi' Little" (231). The surroundings in this picture are well subordinated and made subsidiary to the figure of an old woman sitting by the fireside. "Study of an Old Head" (285), by J. Terras, is commended, but, although showing good work, has little artistic quality. "Peonies" (288), by D. W. Kyle, is also commended. This is a very fine flower study indeed of good colour and sympathetically mounted. This class is probably the

best in the show, and contains much excellent work. Among the pictures that call for attention are "Head of a Monk," a well-posed and lit study by Scott Galloway; two head studies by W. Illingworth, treated in a large, open manner; "A Hand at Cards," a capital flashlight interior, showing a group of countrymen interested in a game of nap; "Devotion," that curious but unassailable figure study by Arthur Marshall; "Grannie's Tired Bairn," and "The Village Doctor," two admirable specimens of J. Hepburn's genre work; "Portrait of an American Lady," an unconventionally striking group of a lady and two children; "A Child Study," by Kate Smith, a beautiful little nude; and three fine male nude studies by F. H. Crossley.

Class J, Architecture, is not a strong class numerically, but contains some sound work. The silver plaque is awarded to Arthur Marshall for "The Last Sleep." This splendid piece of work has been already favourably noticed more than once in these columns, and calls for no further comment than that it is probably the best thing of its kind ever produced by photography. W. H. Mayne secures the bronze plaque with "The Belfry, St. Germans," which is not an altogether satisfactory piece of work. The quality of the print is rather poor, and it is not a very interesting subject. It is saved only by a somewhat dramatic shaft of light crossing the picture. A somewhat similar subject, but one that appears to us to be infinitely better in every respect, is "An Abode of Peace," by W. A. Clark. This is commended only. Other prints worthy of note in this class are: "An Old-time Street," by A. W. Walburn; "The Crypt," by T. Wright, has beautiful quality and softness, but is utterly marred by the too aggressive hand work, which is a failing in many of this worker's exhibits. S. G. Kimber's picture, "The Close Gateway, Winchester," although taken from an excellent and novel point of view, is much too hard. "In Gloucestershire," by P. Bale Rider, an old-world courtyard and houses, is a perfect little specimen of good technique.

Class K, Landscapes, is the largest class in the Exhibition, but cannot be said to be the strongest in quality. It contains much indifferent work. The silver plaque is awarded to A. F. Scott for "The Shore, Llwynrwl," a very pleasing arrangement of hilly shore and rippling waves. The distant hills are admirably rendered and the tones of the whole picture are good. We can hardly understand why the bronze plaque was awarded to No. 387, "When the Leaves have Fallen," by G. H. Capper. This is a very ordinary woodland scene of bare tree-trunks, the composition of which leaves much to be desired, although a nice atmospheric effect is suggested in the distance. There are many much better things in the class. "The Bastioned Crags of Sark," by Bruce Crawford, is commended, but has no great pictorial quality or motive. Bertram C. Wickison's "Vesper Hour" calls for attention in this class, and is a fine piece of work, good alike in composition and execution. Graystone Bird's work, too, is outstanding, but is getting rather hackneyed. It is a pity that this capable worker does not attempt a new style of picture-making for exhibition purposes. His best, because most unconventional, print in this class is "Childhood's Joys," a charming little group of children playing on the sands. The reflections are quite remarkable, and the whole is full of action. C. D. Baxandall has a good thing in "Reflections," but the colour is too hot. C. H. Capper, too, has an excellent composition in "A Summer Flood," but here the extreme fuzziness is a distinct fault in so small a picture. H. C. Leat's "Tower Bridge" shows that structure taken from a novel point of view, and is quite successful. C. E. Walmsley's work is always sincere, and his "Charcoal Burners" is an admirable little picture of men and smoke. Aubrey Harris's "The Prime of Summer Time" is a gem in its way—a glorious little landscape teeming with sunlight and warmth, but rather too much sky is included. H. H.

Luther's "Where Men Toil" gives a vivid rendering of belching chimneys that, although uninteresting in themselves, form a fine, vigorous composition of masses of light and shade. "Shadows," by Arthur Marshall, is an object-lesson in the art of seizing opportunities and making the most of very little material.

In the members' classes, Class A, Portraiture, etc., is not of a very high average. The first bronze plaque is awarded to E. W. Taylor for "Preparing Dinner," a kitchen interior with a very curious and rather unconvincing effect of lighting. The second bronze plaque goes to F. W. Gregg for "The Smith," another interior, in which the lighting is somewhat better managed, but the figure is a little stiff. "The Skipper's Yarn," by C. R. Nicholls, is commended, but does not rise much beyond being a snapshot of a quayside group, and is rather hard.

Class B, Architecture, shows better work, but contains many versions of similar subjects, possibly due to members working in groups at excursions. This is rather to be deplored, as it somewhat discounts individuality. The first bronze plaque goes to "A Norman Crypt," a well-rendered subject by E. R. Bull; the second plaque is awarded to "The Triforium, Gloucester," by F. W. Jeffery, an admirable little print, presumably platinotype of good quality. This subject in particular is duplicated many times and in many degrees of excellence, sizes, and colours in this class, and one of them, by G. J. T. Walford, is commended.

Class C, Landscapes, etc., is a big class, but very unequal in quality. E. Pady takes the first award with "Evening on the Teign," the principal claim to attention being its cloud effect, which is repeated in the water. Gideon Clark and G. Brown are bracketed equal for second place. The former's "Eventide" shows a fine misty effect, which appears to be Westminster taken during the recent fogs. The latter's "Mill on the Common" is a pleasing composition, the rolling clouds being perhaps a trifle too theatrical. J. K. Ayling's silver birch study is commended, and is a pleasing little print of excellent quality.

Class D is devoted to pictures taken during the Society's excursions. This is a good idea, and is apparently quite successful. E. W. Taylor takes the plaque for "At Eventide," and C. H. Pitman is commended for "On St. Paul's Cray Common."

In the lantern slide classes, both open and for members, some good work is shown, some indifferent, and much that is downright bad. The Rev. H. W. Dick takes the silver plaque in the open classes with a set of genre studies, and W. H. Goy is second with a somewhat mixed set. In the members' class E. R. Bull is awarded the plaque for a set of portraiture, and F. W. Jeffery is commended for a set of architecture. In the members' class F. W. Gregg is awarded the gold medal in Class F for pictures medalled between February 1904, and February, 1905, and T. Wright takes the gold medal for the best picture in the exhibition with "Winter." This is a very old stager, and has appeared at many exhibitions during the past three years. It is time Mr. Wright produced another picture to take its place.

In the Novelties Class a bronze plaque is awarded to J. Tufnell Page, of 30, Ash Street, Walworth, S.E., for "The Peckham Universal Enlarging Easel," and a silver plaque is awarded Messrs. Prosser Roberts and Co. for the best trade stall.

In the Edwards Memorial Competition the award (bronze medal) goes to Victor Emmett. A collection of pictures by Dr. C. Grindrod is hung on a separate screen, and pictures by The Autotype Company, C. P. Goerz, and Albert Flint, are shown in the Professional Section.

The trade stalls include some excellent displays of apparatus and materials by Kodak, Ltd.; The Adhesive Dry Mounting Co.; Messrs. Ashford, of tripod fame; J. Barnard and Son, with the velvet method of tinting photographs; A. Alston, with every appliance for

crystoleum painting; Messrs. Bayer; The Wizard Camera Co.; Mann's Drug Stores; and Messrs. Prosser Roberts and Co. The evening displays of lantern slides and lectures are a feature of the exhibition, and every praise is due to the hon. sec., H. Creighton Beckett, and his assistants for the success of the show.

FORTHCOMING EXHIBITIONS.

February 15-March 15.—International Exhibition Artistic Photographs, Vienna. Hon. Secretary, Dr. Reiniger, Camera Club, Largerplatz No. 3, Vienna III., 3.

February 25-March 11.—Edinburgh Photographic Society. Entries close February 11; for pictures, February 15. Hon. Secretary, J. S. McCulloch, 5A, North Saint David Street, Edinburgh.

March 4-11.—South London Photographic Society. Hon. Secretary, H. Creighton Beckett, 44, Edith Road, Peckham, S.E.

March 13-17.—Chemists Exhibition, Covent Garden Opera House. Manager, Chemist's Exhibition, 44-47, Bishopsgate Without, London, E.C.

March 14-17.—Brentford Photographic Society. Hon. Secretary, F. H. Read, Ferndale, Clifden Road, Brentford.

March 16-30.—International Photographic Exhibition, Earl's Court. The Organising Managers, 119-125, Finsbury Pavement, London, E.C.

March 20-25.—The Cripplegate Photographic Society. Hon. Secretary, John B. Parnham.

March 27-April 1.—Leicester and Leicestershire Photographic Society. Entries close on March 20, 1905. Secretary, R. Warden Harvey, Oriental Cafe, Market Place, Leicester.

March 30-April 3.—Chiswick Camera Club. H. Gentry, 39, Fairfax Road, Chiswick.

April.—International Exhibition, Genoa. Sec. Gen., Piazza Fontane Marose 10, Genoa.

April 3-15.—Photographic Society of Ireland. Hon. Secretary, R. Benson, 35, Molesworth Street, Dublin.

April 4-6.—Wallington Camera Club. Hon. Secretary, J. W. Corbett, Nithsdale, Onslow Gardens, Wallington.

April 5-8.—Nottingham Camera Club. Hon. Secretary, S. W. B. Vines, 102, Woodborough Road, Nottingham.

April 7-15.—Photographic Trade Exhibition, Portman Rooms. Baker Street, London, W. Manager Pictorial Section, W. Selfe, 70, Paragon Road, Hackney, London, N.E.

April 7-May 8.—International Artistic Exhibition, Berlin. Director, Herr Franz Goerke, Maassenstrasse 32, Berlin, W.

April 28-29.—Watford Photographic Society. Hon. Secretary, C. J. Trevarthen Ashcroft, Bushey Hall Road, Watford.

May 1-31.—International Exhibition of Photographic Picture Postcards, concurrently with the 10th Salon. M. le Secrétaire Général du Photo Club de Paris, 44, Rue des Mathurins, Paris.

May 9-10.—Ballarat Camera Club. Hon. Secretary, G. Montgomery, 201, Sturt Street, Ballarat.

May 10 to June 19.—Salon of the Photo Club de Paris. Entries close March 1, and pictures must arrive by April 10. Secretary, Paul Bourgeois, 44, Rue des Mathurins, Paris.

June.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

March 31.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Limited, Ilford, E.

September.—Kodak. £400 in prizes for results on Kodak products. Kodak, Ltd., 57-61, Clerkenwell Road, London, E.C.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for Patents were made between February 20 and 25:—

PRINTING.—No. 3,473. "Improvements in apparatus for printing photographs and the like." Kodak, Ltd., 111, Hatton Garden, London. (W. J. Maddox, United States.)

FILM CARTRIDGES.—No. 3,474. "Improvements in photographic film cartridges." Kodak, Ltd., 111, Hatton Garden, London. (Harry Le B. Gray, United States.)

CUTTING PAPER.—No. 3,489. "An improved appliance for cutting photographic paper or other substances." J. Davenport, 15, Limes Grove, Lewisham, London.

MAGAZINE CAMERAS.—No. 3,583. "Improvements in magazine photographic cameras." George Wilkes and A. J. Leeson, 24, Temple Row, Birmingham.

PRINTING.—No. 3,675. "Improvements in apparatus for printing photographs." Howard Elliott, 111, Hatton Garden, London.

DAYLIGHT LOADING.—No. 3,758. "Apparatus for loading photographic cameras with dry plates in daylight." A. H. Clark, Fercliff, Goodwick, Pembrokeshire.

STEREOSCOPIC PROJECTION.—No. 3,998. "A new attachment or apparatus applicable to optical lanterns or like instruments for producing stereoscopic effects in processed pictures." W. H. Everson, 114A, Chancery Lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

VIEW FINDERS.—No. 28,237, 1904. A finder of the reflector camera-obscura type, in which the ground glass is movable parallel to the lens' axis, so that the amount of view included at any dis-

placement can be registered with any given rise of front. The adjustment of the glass of the finder is made by cruciform slots in the cover and guide pins working in the latter." W. Trappill, 24, Mittelstrasse, Aachen, Germany.

French Patent.

NEW PRINTING PAPER.—No. 345,205. July 25, 1904. G. Hauser. Paper or other surface is coated with gelatine containing oxide

of zinc, and is then dipped into a solution of silver nitrate or citrate. Fine black tones are obtained by direct printing, and without toning, and hypo does not alter the colour. Under exposed prints can be developed in the usual way, and the paper can be worked by artificial light.

New Materials.

Multiple Plates for Three-Colour and Two-Colour Work. Made by Dr. J. H. Smith and Co., Zürich-Wollishofen, Switzerland.

As announced elsewhere in this issue, new materials for photography in colours are just coming upon the market, in the shape of plates coated with two or three films of different colour-sensitiveness. We write without having handled samples, but we take it that the new Smith colour plate is made according to Dr. Smith's recent patent, No. 19,940, 1904. According to the specification, the plate consists of two or more sensitive emulsions, which are coated each upon a single transparent support. Between each two adjacent layers a thin neutral transparent stratum of collodion or celluloid is interposed, in order to provide for the separation of the sensitive films. Such a compound plate is exposed at one single operation, and the three negatives are then obtained by dissecting the films and developing. It is claimed for the Smith multiple plate that the orthochromatic and other properties of the emulsions are so adjusted that screens are dispensed with, and instantaneous exposures may be given. Such a process opens up new possibilities in colour photography for the million, inasmuch as the whole of the operations subsequent to the actual exposure can be delegated to experts. We hope to report further on the new plates when we have had them through our hands.

The Connoisseur Album. Made by Chas. Tyler and England Brothers, Limited, 79, Copenhagen Street, Caledonian Road, London, N.

Last year this firm brought out a series of mounts which proved very successful. They were called the Connoisseur mounts, and took the form of sheets of thick, rough paper, with deckled edges, and made in various agreeable tints. The novelty about them was the inclusion with each packet of mounts, smaller pieces of thin, smooth paper of the same series of colours as the larger mount, on which the photograph could be mounted in such style as the photographer desired, and then affixed to the large and rough sheet; or more than one of these smaller pieces could be used, so as to form a series of tints surrounding the print.

This excellent method of enhancing the value of a photograph by means of suitable tinted borders now forms the basis of the Connoisseur Album, which is nothing more or less than a collection of Connoisseur mounts bound together in a neat cover, and as a means of tastefully bringing together a series of prints, is all that can be desired.

We have received from Messrs. Edwin Osborne and Co., manufacturers of photographic mounts, 26, Red Lion Square, London, W.C., a sample of their new plated rule mounts. These mounts are intended to take the place of the old-fashioned plate-sunk mounts, and are exceedingly neat and attractive. The space on which the print is to be mounted is surrounded by an impressed rule or die, and the effect gained is very high class. These mounts are made in cream, grey, or white, also for circular photographs. The prices for the mounts are very reasonable, as will be seen from a reference to Messrs. Osborne's advertisement on another page.

New Apparatus, &c.

The Cooper Hewitt Mercury Vapour Lamp. Made by the Cooper Hewitt Electric Co., New York, and sold by Penrose and Co., 109, Farringdon Road, London, E.C.

The tendency to rely wholly or partially on artificial light, instead of upon the fickle British daylight, is one which steadily becomes more marked in the practice of photographers. Other circumstances permitting, there is always the tremendous incentive to adopt artificial light *in toto*, that the studio can be brought down to the street level, and the series of carefully-disguised truths which a fourth-floor photographer must perpetrate in cold print in order to raise his patron floor by floor to his studio, need be seen no more. The certainty which artificial light confers upon the lighting of the sitter is scarcely of greater importance than this literal lowering of the status of the studio. For these reasons, every substitute for daylight offered to photographers deserves at the least a fair investigation, and such should certainly be accorded to the latest claimant for notice—the mercury-vapour lamp. Recent articles in this journal will have made our readers conversant with its chief properties, among which we emphasise the considerable

Studio Light of Mercury-Vapour Lamps.

Installation of Mercury-Vapour Lamps for Printing.

illuminating area and the manner in which that area can be lessened or increased by taking from, or adding to, the number of lamps. Many varieties of lamp are made by the Cooper Hewitt Electric Co., and two of them are here illustrated by permission

of Messrs. Penrose and Co., who are making themselves responsible for the supply of installations in Great Britain and elsewhere. The lamps, it will be seen, can be put up to replace any given area of studio light, but possess the advantage of mobility and controllability in power. In photographic printing, enlarging, etc., there is undoubtedly a field for the new lamps, and a description of the various types with other technical particulars are contained in booklets which we presume Messrs. Penrose will send upon application. The prices of the outfit (lamps, resistances, etc.), as supplied by Messrs. Penrose, range from £7 10s. to £50.

Messrs. Elliott and Sons, Ltd., Barnet, Herts, have sent us samples of their "Owl" toner for Bromide prints. A report on this preparation will appear in our next issue.

The Altrincham Rubber Co., Altrincham, remind us of their useful specialities by sending us their latest catalogue, a copy of which they will post on application.

RECEIVED.—Roto P.O.P. (The Rotary Photographic Co., Ltd.). A printing-out paper of hard emulsion, for which immunity to warm solutions is claimed. We shall report upon it in due course.

PORTRAITURE of the feet is reported as the fashion in American photography. Ladies are taken in the smartest stockings and shoes, with just a few ruffles of the petticoat showing, or as nature made them, without any covering, resting on a velvet cushion, with a hint of lingerie above. We should imagine that the ladies must come to an "understanding" with the photographer before the delicate operation is performed.

THE Southampton Camera Club's scheme for a photographic record and survey of Southampton has assumed a definite shape, and circulars have now been issued to all members seeking their co-operation in obtaining a representative collection of photographs, executed in a permanent process, of all objects of local, historic, or antiquarian interest connected with Southampton, with a view to asking the town's acceptance of them, to be permanently exhibited in a public building. For the present it is not proposed to extend the area of the survey beyond the ancient walled town and its immediate surroundings, and to this end a sketch plan of the district is included in the circular. This is an admirable idea, as it enables the members to ascertain at once the places of interest of which photographs are required for the collection.

At the Croydon Camera Club recently Mr. Hugh Allen showed a capital method of mounting large prints without cooking. No claim to originality was made, and, as a matter of fact, the main idea is by no means new. The print to be operated upon is first placed on a board, and the back coated with adhesive, the particular one suggested—and to which, by the way, exception might be taken—being three parts of strong gum solution to one part of fish glue. When dry the print is trimmed, and will remain flat. Its position can then be marked on the mount. A sponge moistened with water is next passed rapidly over the mount, so as to slightly damp the surface; the print is quickly adjusted to the marks and pressed into contact between two glass plates, the same size as, or larger than, the mount, and a weight applied. The last factor was supplied by Mr. Allen placing a chair on the top glass and reposing therein for five minutes. He claimed for the method: Cleanliness, there being naturally no tendency for the gum to spread; accuracy, for the print, being dry, of a necessity registered with the marks on the mount; and, lastly, an entire freedom from curl, all of which claims were substantiated in the mounted print Mr. Allen produced.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held March 8, Mr. Leslie Clift in the chair. The Secretary (Mr. J. McIntosh) gave a demonstration-lecture on "Intensification and Reduction," in which he described the after-treatment advisable to make the best of errors in exposure and development. The operations and formulæ were as follows:—

Correctly Exposed: Under-developed.—Bleach in a saturated solution of mercuric chloride containing $\frac{1}{2}$ per cent. of hydrochloric acid. Wash well in a $\frac{1}{2}$ per cent. solution of hydrochloric acid, wash in plain water, and blacken in formaline, 34 minims; sodium hydate, 10 grains; water, 4 ounces.

Correctly Exposed: Over-developed.—Reduce in a 2 per cent. solution of ammonium persulphate containing $\frac{1}{2}$ per cent. of sulphuric acid, rinse in 5 per cent. solution of sodium sulphite, fix in hypo, and wash well.

Under-exposed: Under-developed.—Intensify with Lumière's Intensifier as follows:—Mercuric chloride, 1 grain; potassium iodide, 3 grains; sodium sulphite, 40 grains; water, 1 ounce. Develop with any clean-working developer and wash.

Under-exposed: Over-developed.—Reduce in a 2 per cent. solution of ammonium persulphate as above, and intensify with Lumière's Intensifier as above.

Over-exposed: Under-developed.—Intensify with Monckhoven's

Intensifier as follows:—(A) Mercuric chloride, 100 grains; potassium bromide, 100 grains; water, 10 ounces. Bleach in this and wash well. Then blacken in the following, mixed together: (B) Silver nitrate, 100 grains; water, 10 ounces; (C) potassium cyanide, 100 grains; water, 1 ounce. As soon as the blackening is complete wash at once, and thoroughly.

Over-exposed: Over-developed.—Reduce in the following solution: Sulphuric acid, 8 minims; potassium permanganate, 16 grains; water, 10 ounces, and wash thoroughly. Brown stains may be removed in a dilute solution of oxalic acid.

Halated Negatives.—Bleach in the following:—Chromic acid, 30 grains; potassium bromide, 60 grains; water, 10 ounces. Wash thoroughly in several changes of a 5 per cent. solution of potassium meta-bisulphite, and then in plain water. Partially re-develop in any clean-working developer, fix at once, and wash thoroughly.

LIVERPOOL AMATEUR PHOTOGRAPHIC ASSOCIATION.

ON March 2 Mr. Page Croft demonstrated the gum process to the members of this society. He began by saying that the photographers of Liverpool were falling behind, and were not supporting "pictorial photography" in the way they ought to do, and suggested that it was the innate conservatism of Liverpool which prevented even advance in this direction.

Mr. Croft then asserted that "gum" was not only the best, but the "only" photographic process; that it had all the advantages and none of the disadvantages of carbon. He could do with it everything that any other process could do, and then he could go further and do more. He intended to "have" Liverpool in the cause of gum, and he wished to start in it a "photographic revival" worthy of the great city.

Mr. Croft then gave a most interesting demonstration, describing the process fully and developing many prints. At the close Mr. Croft offered to give an award at the next annual competition to the best work in gum.

SOUTHAMPTON CAMERA CLUB.

MR. ORMISTON SMITH lectured before the members of this club on Monday last, his subject, "Mountaineering Life," attracting considerable attention, inasmuch as it was illustrated throughout with some unique bioscope pictures. The lecture dealt in realistic fashion with various perilous climbs undertaken by Mr. Smith and his party, the dangers of which must have been considerably augmented by the carriage of the camera for securing the animated pictures. The ascent of Mont Blanc, the Jungfrau, and the Matterhorn, were all treated by this method of portrayal, and proved of more than ordinary interest.

A run over the entire length of the Gormer Grate Railway, and a moving picture showing the rush of an avalanche were among the novelties, while films fully illustrating the dangers of mountain climbing were also shown. Ordinary slides of great merit were interpolated between the display of animated pictures, and Mr. Smith concluded his lecture with pictures of the Swiss sports, skating, tobogganing, etc., the humour of which afforded an excellent foil to the tension brought about by some of the preceding representations.

DERBY PHOTOGRAPHIC SOCIETY.

THE seventh meeting of the winter session was held on Monday evening last, in Messrs. Cumberlands' room, the Wardwick, when Mr. W. R. Bland, F.R.P.S., delivered an interesting and practical lecture on "The Production of the Exhibition Print." Mr. Bland showed at the outset that the possession of valuable apparatus had less to do with the production of pictorial photographs than skill

and taste in the choice of subject and in the manipulation of the enlarged negative and print. Any lens would yield good results if the man behind the camera understood it. In the making of the print, what was needed was a synthesis and not an analysis of the scene photographed. The lecturer demonstrated the advantages of obtaining the enlarged negative, by contact from an enlarged positive, and showed how by the use during printing of masks cut from unsatisfactory prints he had succeeded in producing many of his own successful pictures.

LONGTON PHOTOGRAPHIC SOCIETY.

THE annual meeting of the Longton and District Photographic Society was held at the Sutherland Institute on Thursday last. Dr. A. Parkes, J.P., presided. The Secretary (Mr. T. Mottershead) presented a satisfactory report. A statement of accounts, which was accepted as also very satisfactory, showed the society had a credit balance of £32 3s. 3d. The exhibition realised a profit of £1 19s. 4d. The Secretary said the financial position of the society was eminently gratifying, and it was pleasing to recall that during the society's existence nearly £50 has been raised for public institutions.

The following officers were re-elected:—Dr. A. Parkes, president; Rev. C. F. L. Barnwell and Mr. A. W. Allin, vice-presidents; Mr. S. Ashcroft, treasurer; Mr. T. Mottershead, secretary; and Mr. A. Shenton, auditor. The following were chosen as the committee:—Messrs. T. Lawrence, B. J. Allen, J. Toft, W. H. Foxall, W. Bates, E. Carratt, and G. V. Myatt.

WINDSOR CAMERA CLUB.

THE annual meeting of this club was held at the Royal Albert Institute, Windsor, on Tuesday evening last.

The report for the last twelve months was read, and proved satisfactory, and the balance-sheet showed a small balance on the right side.

Mr. Southcombe May sent in his resignation of hon. secretary and treasurer, owing to his leaving Windsor. Thanks are due to him for having taken the first steps towards the foundation of the club.

Mr. Harrison, together with Mr. Oetzmann, was re-elected delegate to the Royal Photographic Society, and Mr. T. J. Cartland was elected hon. secretary.

Last year's committee, Messrs. J. W. Cooch, G. P. Cartland, C. C. Harrison, and S. Holderness, Mrs. Hartley, and Mrs. Buckley, were re-elected, with the addition of Mr. Trotter. It was also resolved to invite Lord Edward Spencer-Churchill to become a vice-president.

DUNDEE PHOTOGRAPHIC ASSOCIATION.—At the last meeting a lecture was delivered by Mr. John MacLachlan, entitled "Photography with a Purpose." The lecturer laid stress on the fact that in photography, as in all other pursuits, the man at the top is always a specialist. The photographer should decide before setting out what his subject is to be, and not allow himself to be tempted from it.

SLOUGH PHOTOGRAPHIC SOCIETY.—Mr. M. Rouse demonstrated Auto-Pastel before this society last week. From his experience he found that the exposure should be about 25 per cent. less than for carbon tissue, this being due to the thinness of the pigment and small proportion of colloid. Great care should be taken to avoid over-exposure. Mr. Rouse developed a number of prints, many of them local views taken in Burnham Beeches, and which fully justified the artistic claims of the paper. A sensitising bath of $2\frac{1}{2}$ per cent. bichromate of potash was recommended.

Commercial & Legal Intelligence

S. POPERT AND COMPANY, LIMITED.—Capital £1,000 in £1 shares. To carry on the business of manufacturers of and dealers in phonographs, gramophones, records, phonograms, cinematographs and films therefore, and similar instruments, etc. No initial public issue. S. Popert is the first director. Qualification, 500 shares. Remuneration as fixed by agreement. Remuneration of other directors as fixed by the company. Registered office:—24, High Street, Manchester.

HARRY H. HAMILTON, LIMITED.—Capital, £2,000 in £1 shares. To acquire the business known as "Hamilton's Original Excursions and Panstereorama of Passing Events," carried on at Manchester, Birmingham, and elsewhere, and to carry on the business of diorama and panorama proprietors, music hall and theatre proprietors, cinematograph and mutoscope proprietors, etc. No initial public issue. The number of directors is not to be less than two nor more than five. The first are:—H. Hamilton, and G. H. Hamilton. Qualification, £50. Remuneration as fixed by the company.

JASPER REDFERN AND Co., LIMITED.—Registered February 24. Capital, £3,000 in £1 shares. Object, to acquire the business recently carried on at 53 to 57, Surrey Street, 104 and 106, Norfolk Street, both in Sheffield and elsewhere, as Jasper Redfern, Limited, to adopt an agreement between H. Jasper Redfern and G. W. Lloyd of the one part and E. Brook of the other part, and to carry on the business of opticians, refractionists, manufacturers of optical, photographic, and scientific instruments, photographers, experts in animated photography and Rontgen rays, electricians, public entertainers, etc. No initial public issue. The first directors (to number not less than two nor more than five) are Jasper Redfern, G. W. Lloyd, and G. Mettham. Qualification, £1.

A PHOTOGRAPHER'S BUSINESS.—At a sitting of the Brighton Bankruptcy Court on Thursday last, before the Registrar (Mr. A. O. Jennings), William Avenell, trading as W. Avenell and Co., of 48, West Street, Brighton, photographers, was examined by the Deputy Official Receiver. The debtor said his liabilities were £682 and he estimated that his assets would produce £520. During the last two years, he had had very bad trade, and he found it impossible to pay his way on his turnover, although in 1903 his gross takings were £1,495. Last year they had fallen to £1,000. When he went into the photographer's business he borrowed £1,200, and that he had never been able to repay, but he had paid the interest regularly. The examination was closed.

A NEWSPAPER'S ADVERTISING SCHEME.—Mr. Gustave Auerbach, a photographic manufacturer, 15, Houndsditch, sued the Pictorial Newspaper Company, Limited, the proprietors of the "Daily Mirror," to recover £180 odd, made up of £134 for breach of contract, and two sums of £31 10s. and £14 8s., the loss on pendants and brooches obtained by plaintiff for the purpose of completing his contract. The case for the plaintiff was that the defendants agreed to employ him to supply all the miniatures and brooches required for the "Daily Mirror" under a scheme submitted by him to them. On the ground of delay in the execution of orders, the defendants, it was said, put an end to the employment without notice—hence the action. Besides damages an injunction was claimed to restrain the defendants or their agents from employing any other person than the plaintiff to supply the miniatures required for the paper. The plaintiff denied in his evidence that there had been any delay, and it was argued on his behalf that, even if he did make default in his contract, it did not entitle the defendants to repudiate it. The Common Serjeant, after hearing the evidence, gave judgment for the plaintiff for £150.

News and Notes.

CROYDON CAMERA CLUB.—On Wednesday last a practical demonstration of the manipulation of the projection lantern and the oxy-hydrogen limelight was given before the members of this club by the President (Mr. W. H. Smith).

PHOTO ART CLUB, ABERDEEN.—A lecture on "Architecture" was delivered by Mr. David, at Gray's School of Art, last week. With a large number of excellent slides Mr. David explained the features of the various styles of architecture, beginning with the ruined Doric Temples of Athens, and showing the characteristics of Ionic, Corinthian, Roman, Byzantine, Romanesque, Norman, Gothic, and Renaissance or Elizabethan. The club has affiliated with the Scottish Photographic Federation.

ART in Advertising.—Over 500 specimens of advertisement display are now on view at 134, Salisbury Square, Fleet Street, E.C. They are the exhibits sent in in connection with a £500 prize competition promoted by Mr. Walter Haddon and the editor of the "British Printer," with the object of encouraging a wider interest in effective and artistic advertisement display, an important condition being that all the types and borders used should be British made.

THE Photographic Convention.—The first meeting of the Reception Committee in charge of the arrangements in connection with the visit in July next of the Photographic Convention of the United Kingdom was held on Thursday last in the Leinster Lecture Hall, Molesworth Street, the Earl of Rosse, K.G., presiding. On the motion of Mr. Thos. Mayne, seconded by Sir Howard Grubb, the following resolution was passed unanimously, viz.:—"That this meeting approves of the action of the Photographic Society of Ireland in inviting the Photographic Convention of the United Kingdom to hold its annual meeting for 1905 in Dublin, and pledges itself to use every effort to secure the success of the convention." Sir Howard Grubb and Mr. J. A. C. Ruthven were appointed hon. treasurers.

PHOTOGRAPHY Past and Present.—The President of the Scottish Federation, Mr. G. D. Macdougald, gives some interesting reminiscences in the current issue of "The Secretary's Letter." As a boy, "he remembers having spoken on photographic matters with the aged Fox Talbot at a time when, in order to possess a few ounces of the precious fluid called collodion, we made with our own hands the gun-cotton and redistilled the ether and alcohol. A time when only an occasional wet plate was developed with a new and strange material—pyrogallie acid—costing one pound sterling per ounce." Such a comparison as this shows the immense advance made since that time, and when it is remembered that dry plates as we now know them were then unknown, it helps to a better understanding of the conveniences of to-day, and the consequent popularity of the camera.

MR. JOHN MACKENZIE, an experienced photographic operator of the Urban Trading Co., will accompany Mr. Harry de Windt, the celebrated explorer, on a very interesting expedition which is to be made shortly. Mr. de Windt, with Mr. Mackenzie, starts from Cattaro, on the Adriatic coast, in Montenegro, and will ride from there to Nisch (Serbia), which is famous for a tower of human skulls. Mr. de Windt then makes his way to Belgrade, returning thence to Sofia, in Bulgaria. From that place he will strike northward in the direction of Bucharest. Near Jassy (Roumania) he crosses the Russian frontier, and will skirt the northern shores of the Black and Azov seas to Rostov, on the Don. He also proposes to visit Tiflis, and to cross the precipitous ranges of the Caucasus. Mr. Charles Urban anticipates that some

unique and vastly interesting films will be the result of this expedition.

THE third annual meeting of the Photographic Survey of Surrey is fixed for Saturday, March 11, when the President, Viscount Midleton, will address the meeting on the work of the Society in the Council Chamber of the Town Hall, Croydon, at 5.45 p.m. The meeting is open to all who are interested in recording by photographic means the notabilia of the county. During the evening, and until the 15th inst., a representative selection of the thirteen hundred prints in the Survey collection will be shown in the Town Hall Lecture Room, and a short lantern lecture will be given each day illustrated by specially interesting examples of subjects in the collection. Surrey residents having prints depicting anything relating to the county which is worth preserving, are invited to forward them for addition to the collection to the hon. secretary, Mr. Harry D. Gower, 55, Benson Road, Croydon. Prints by any process are accepted, but preference is given to carbon, platinotype, or bromide.

THE King's Portrait in Politics.—"I had some talk to-night with Mr. W. Downey, of the great photographic firm of W. and D. Downey, of Ebury Street," writes a correspondent to the "Yorkshire Daily Observer." "The Downeys, as you know, have been photographing the Royal Family since quite early days in the history of photography. Mr. William Downey brought to my notice a newspaper paragraph in which it is stated that a Yorkshire clergyman has written to the King calling his attention to a political manifesto in the Barkston Ash Division. It is in the form of an almanack bearing portraits of His Majesty, Mr. Arthur Balfour, and Mr. Joseph Chamberlain. The description suggests the Tariff Reform League, or 'Consistent Birmingham,' as the originating source. The Yorkshire clergyman pointed out that the King's photograph is being used for political purposes, and His Majesty's private secretary has replied that steps have been taken to prevent the use of the Royal portrait in this manner and to serve these uses. Mr. Downey says, in fact, His Majesty is very much irritated at his portrait thus being put to party uses. There is one way of putting an effectual end to anything of that sort. Photographs of the King are copyright, and if the Yorkshire clergyman will communicate with Mr. Downey, giving him necessary particulars, something may take place which will make it inadvisable in future to represent the King as a factor in party politics."

THE modern society photographer would be brave indeed if he adopted the methods of the portraitist in the anecdote related in the current number of "The Lady's Pictorial":—"On one of the large P. and O. boats going to Australia there happened to be a Chinese artist noted for his quick portraiture. He was soon surrounded by a crowd of the fair sex, who wished to have their portraits painted. He, not unwilling to turn an honest penny during the tedium of the voyage, agreed to make rapidly finished sketches of each sitter. He asked each lady whether she would have the portrait 'handsomey-handsomey,' or 'likey-likey.' Not one of the sitters had the moral courage, in the presence of the sterner sex, to admit what was doubtless the desire of their hearts, so said they wished them 'likey-likey!' Now, the Chinese are remarkable for their extreme fidelity in copying, so when each sitter was rewarded with a representation of herself, the result was not always as pleasing as could be wished, and many of the paintings were successfully smuggled from the saloon, and surreptitiously dropped overboard in the dead of night. One lady, braver than the rest, remonstrated with John Chinaman on the ugliness of her portrait; he explained in his pigeon-English that he had 'askey likey-likey or handsomey-handsomey—no handsomey, if likey, how can?'"

Correspondence.

- * * Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given
- * * We do not undertake responsibility for the opinions expressed by our correspondents

AN APPEAL TO CHARITY.

To the Editors.

Gentlemen,—About two years ago you were good enough to allow me to appeal through your columns on behalf of a poor ex-professional photographer, bed-ridden for very many years, and supported only by a small weekly dole from "the parish," and such little money as a devoted daughter (who is his nurse and sole attendant) can earn. This case had been thoroughly investigated by the Photographers' Benevolent Association, which gave a small grant weekly during the last few years of its existence. The response to my appeal was very good, and as some of the contributors promised weekly or monthly subscriptions I hoped that it would be possible to continue sending the little weekly sum for the rest of the poor photographer's life; but, unfortunately, the regular contributors felt the pinch of bad trade; so that now only one continues, contributing 13s. per quarter. The accumulated fund is quite exhausted, and what I now earnestly ask is that a few of those who can afford it will send me further contributions, however small, or, if possible, promise an annual sum. Two shillings a week (in addition to the sum already coming in) will maintain our pensioner in his independent position, free from the work-house; and four shillings a week will keep him in what he, poor man, considers real affluence. Only £10 8s. a year is needed for the greater object. Though he has not touched camera or printing frame for many years he keeps up his interest in the craft by reading the journals and books which are sent to him regularly by some who cannot contribute much in money.

Enclosed is a balance sheet, properly verified for your own information. A copy has been sent to each of the old contributors. I make this appeal in the hope that it may have such response as will render its repetition quite unnecessary.—Yours faithfully,

H. SNOWDEN WARD.

February 28, 1905.

BRITISH POSTCARDS.

To the Editors.

Gentlemen,—You write from time to time in the BRITISH JOURNAL OF PHOTOGRAPHY about good ideas which should occur to photographers, so as to increase their trade. I suppose these hints are eagerly taken up, considering that the Englishman is a tradesman from birth and not liable to let any chance of making money slip away.

Here is an illustration of a case in point. You hinted several times at the way businesses could be enlarged by addition and sale of illustrated postal cards. French picture cards are, I think to be found in England. So far I have been unable to trace one here in Paris. Some time ago I asked, through your kindness and "Answers to Correspondents," to give me the name of a firm publishing some English postal cards of a certain subject. You kindly answered by giving me the names of three likely firms. I wrote to all three asking for catalogue and prices. Result is not very satisfactory so far. After three weeks time I received one letter from a firm. This letter, stamped with a penny stamp, instead of 2½d., and leaving an expense of 3d. to pay here, contained a few lines, stating that an enclosure was made of a price list and a few samples; but unfortunately these enclosures were totally absent. This for No. 1.

The other firm forwarded my address to another firm in Switzerland, which in turn sent me a catalogue of Swiss views only. Imagine the beauty of my asking for English views and to have to go to a village in Switzerland for them, and receive another catalogue of what I do not ask for. This settles No. 2.

No. 3 has not answered at all. Is not this way of doing business quite English? It seems to me, however, that there are such views published in England, and that they should be found in a small village like Paris without having to go to Switzerland for them, and not receive them even then.

I received lately a catalogue from a firm in Detroit, Mich., U.S.A., giving a certain quantity of views (coloured), taken in England. I suppose I will have to order in this roundabout way to get views, two or three hundred miles distant, from a place about four thousand miles away.—Yours truly,
A. LEVY.

P.S.—Since I wrote the above I received full explanation and rectification from parties forming item No. 1, which proved satisfactory.

A. LEVY.

4, Avenue Pinel, Asnières (Seine).

March 4, 1905.

[Our correspondent's experience is surely exceptional, for postcard publishers in this country, so far as our knowledge of them extends, may be aptly described in the Gilbertian phrase of "pressing prevailers." Probably the publication of his letter will acquit them, in Mr. Lévy's eyes, of the charge of apathy which he brings against them.—Eus. B.J.P.]

ROYAL Photographic Society.—At the next meeting of the R.P.S., on March 14, Mr. D. S. Chalmers will lecture on "Some Results of Lens Testing."

THE "Furniture Times" is a publication which Mr. Carl Hentschel, who issues it during the present furniture exhibition at Earl's Court, is anxious to dissociate from the organ of Printing House Square. "The Times" has gone into the furniture trade only in the matter of book-cases for encyclopedias, and the "Furniture Times" exists only to point out, in a mean, underhand, amusing, and eminently successful way, how furniture firms can promote business by good half-tone and three-colour illustrations. Hentschel, colourtype, and Meisenbach are words that crop up in every paragraph and in advertisements in the "Furniture Times," but the issue is none the less good reading, and in its way a model of artistic advertisement.

THE work of John W. Alexander, an American artist of note, is the subject of an article in the current issue of "The World's Work and Play." It is more particularly to the illustrations accompanying the article we would draw the attention of figure photographers in search of new poses and effects. Expression of gesture and movement appears to be the chief aim of this artist's work, which is characterised by a mingling of reticence with spirit, while with his female figures, of which the illustrations chiefly consist, he shows a frequent partiality for large, balloon-like masses of skirt, which lend a certain discreet voluptuousness to many of his compositions.

WELSH Water and Photography.—A correspondent of the "Birmingham Daily Post" asks if any photographic readers of that paper have had any trouble with bromide prints since Welsh water has been in Birmingham. He says: "I have lately done some prints on a well-known bromide paper, and have been greatly troubled with blisters. Some I have just done are absolutely covered with blisters of from $\frac{1}{8}$ in. to $\frac{3}{8}$ in. in diameter. I do not know yet if it is the fault of the water or if I have got some very old paper." Possibly Mr. Harold Baker's article on "Blisters on Bromide Paper" (B.J., February 17) would prove of assistance, especially as Mr. Baker himself is a Birmingham photographer.

Answers to Correspondents.

- *.* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- *.* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- *.* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.
- *.* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED.—

PURCELL AND BETH.—Grove Works, Lombard Street, Battersea, London, S.W.

J. A. D. LLOYD.—(Kodaikanal, India), Penrose and Co., 109, Farringdon Road, London, E.C.

T. A. M.—You should address the various producers of films, such as the Urban Bioscope Co., London, W.; Messrs. Williamson's, Brighton, etc.

E. H. GIBSON (Burton-on-Trent).—There is "Enamelling and Retouching," by P. Piqueppe, price 2s. 6d., from Dawbarn and Ward, 6, Farringdon Avenue, London, E.C. We believe the "Art of Photographic Painting" is still in print.

OTHELLO.—Yes; your circular marks are flare. Carefully examine the lens to see that there are no bright reflecting surfaces inside the tube, if there are any blacken over. You would be able to see these patches if you focus a lamp in a dark room, and could probably get rid of them by slightly unscrewing one, or both, of the combinations, thus altering the distances.

GROUND GLASS PAINT.—Can you supply me with address of the firm in London who, I believe, have put on the market a paint which gives the same effect as ground glass?—A. E. STANLEY.

We cannot. Ordinary white lead paint, dabbed on with a short brush, will answer for obscuring glass windows. There are a number of ground glass varnishes on the market, but these, we take it, are not what you require.

F.R.P.S.—Will you kindly inform me what one has to do to gain the letters F.R.P.S.?—A. A. SCOTT.

The Fellowship of the R.P.S. is granted to persons applying for it in recognition of services rendered in the advancement of photography. The secretary of the society (66, Russell Square, London, W.C.) will send you a circular explaining what these services may be.

H. SPARROW.—The results are certainly very good, although there are processes for giving similar tones. We think the general

character of your prints are superior to their results. But we are very doubtful as to the process having any commercial value, because the demand for such tones is very limited. You might offer it to makers of chemical specialities for photographers whose names you will find in our advertisement pages.

GASLIGHT PAPER, PRINTED-OUT.—In printing-out a piece of Velox (bromide) by daylight, I find it prints a violet colour. Is there any formula for making it permanent?—S. J. W.

If the paper is very thoroughly printed out—say, by exposure for an hour in bright sunshine—the print can be fixed in the ordinary hypo bath, the colour being thereby somewhat altered. But why torture the process in this fashion?

ANATOMY IN RETOUCHING.—I am greatly obliged to you for having put me on to the "Art of Retouching," by R. Johnson. Would you now do me the further kindness of telling me where I can get a book describing the anatomy of the human face in detail, by means of illustrations?—L. B. HAWKES.

"Retouching," by Arthur Whiting, in other respects an excellent book, is the only one we know which deals with and illustrates retouching on anatomical lines. It is published at 1s., by Dawbarn and Ward, Ltd., 6, Farringdon Avenue, London, E.C.

GOLD CHLORIDE.—Will you kindly state the chemical composition, giving notation of the above salt as sold in tubes for toning, showing how it contains 7 grains Au., and also please say how a toning solution may be made up from pure metallic gold in the form of brown powder?—TOM HEATH.

The formula of commercial gold chloride is $\text{HAuCl}_4 \cdot 4\text{H}_2\text{O}$. The combining weight of this compound is 412, and as the atomic weight of gold is 197 the formula corresponds with 7 grains of gold in 15 grains of the substance. (2) The gold is dissolved in aqua-regia (2 parts hydrochloric acid and 1 part nitric acid), the solution evaporated to dryness on a water-bath to expel the acid and dissolved in water. You may calculate that 1 grain of the gold forms 2 grains of chloride, but unless you have some chemical experience you had much better buy your gold chloride.

COPYRIGHT.—A friend has lately sat to me for some genre photographs I was making, without payment either to him or to me, but simply to oblige me as a model. Can I now publish or dispose of these photographs without first obtaining my friend's permission? In other words, does the copyright in these photographs belong exclusively to me, and can I do as I like with them? Is it necessary to register the photographs, and, if so, can I then publish or otherwise dispose of them without a specific permission from the sitter?—T. TREE.

The copyrights are exclusively yours. As to the use you can make of them, you are limited only by common law. Your sitter cannot hinder, so far as copyright is concerned, but if you employ the photograph to his, or her, moral, social, or commercial disadvantage, action may be taken against you. You should register the copyrights to legally establish your proprietorship in them.

PLATINUM PRINTING.—I enclose three prints (platinotype), and shall deem it a great favour if you will tell me (1) the cause (or causes) of the stains on them, (2) your opinion of the work.—G. E. G.

(1) As to the prints which we have numbered on the back, negatives Nos. 1 and 2 are probably very thin, and the paper has the appearance of being somewhat old or slightly damp. Increased contrast can be obtained by adding one grain of bichro-

mate of potash to every twenty ounces of developer; in no case must more than two grains be added, or the paper will yellow in time. The effect of the bichromate will wear off. This can be rectified by the very cautious addition of the chemical. The markings are due to dirt, defining dirt as "matter in the wrong place." Probably the paper has been allowed to come in contact with some contaminating substance, laid down on a dirty table, for instance. The defects are probably not due to any fault in the paper. The sky in print 1 shows indications of scum on the developer. This should always be skimmed before use, and it is wise to rock the dish between each development. This print also shows finger marks, indicative of careless working. Print 2 looks as if it had been scraped against metal. The storage tube must always be lined with paper. (2) The prints are not up to a good standard of platinum work. More care is needed, we think, as to the dryness of the paper.

BUTTON PICTURES.—COPYRIGHT.—(1) I shall be glad if you will give me information as to the manner in which celluloid is attached to the front of photographs for making buttons. Liquid gelatine does not attach itself with moderate pressure to the celluloid, and the print attached in this way can be peeled off with a slight effort. (2) I have a registered photograph copyrighted by me some time ago. A local stationer has lately had it reproduced as a postcard by some London firm, and is exposing it for sale in his window, and acknowledges having sold some grosses of them. There is no question about my right to protection, as the photograph was taken without payment being made to me. I am not at present a member of the Photographers' Association, although I intend joining. Will the association take up the matter for me when I am a member? I take it I can proceed against both the stationer and the firm who actually did the work of copying? What would you suggest as a fair amount to claim for damages, as no doubt the infringement has interfered with the sale of the photographs themselves.—H. S.

(1) The print is dipped in alcohol and the celluloid disc pressed in contact with it by a hot roller. The celluloid is thus softened and the print cemented. If you write Jonathan Fallowfield, 146, Charing Cross Road, London, W., he will send you book descriptive of the process and apparatus. (2) The case is one which we should think the P.P.A. would move in on your behalf. You can proceed against both parties. As we know nothing of your sales of the prints it is not possible for us to name a sum for damages.

NOTICE.

Several replies are held over for insertion next week.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

The British Journal of Photography.

The Oldest Photographic Journal in the World.

ESTABLISHED 1854. PUBLISHED EVERY FRIDAY. PRICE TWOPENCE.

TERMS OF SUBSCRIPTION. Post Free (UNITED KINGDOM AND THE CHANNEL ISLES).

EX CATHEDRA.

For the past four days an exhibition of instruments, promoted by the Royal Meteorological Society, has been open at the house of the Institution of Civil Engineers, Great George Street, Westminster, and will have repaid any photographer who has chanced to visit it. He will have seen how largely the photographic method is employed in registering climatic variations. Among other exhibits is the kite camera and cage used in the Scottish Antarctic expedition, an ordinary Goerz-Anschütz instrument, with electric release for its focal-plane shutter. The exhibition closes to-day (Friday) at five o'clock.

Celluloid and Xylonite Risks. For the safety of premises where celluloid and xylonite are stored or worked a memorandum has been issued by the Home Office in which the following precautions are advised:—(1) Where large quantities of xylonite or celluloid are stored, fireproof rooms should be provided. (2) Where xylonite or celluloid is used, or temporarily stored, the material not in actual use should be kept in metal or other fireproof receptacles. (3) Xylonite or celluloid shavings or dust should not be allowed to accumulate on the floors, but should be swept up daily and placed in receptacles of non-inflammable material, not in the sacks or wooden boxes now commonly employed for the purpose. (4) The use of naked lights should be avoided as far as possible; used at all they should be at least 3 ft. from any boring or glazing machine.

Optical Convention. Photographic optics do not figure prominently among the papers set down for reading at the Optical Convention, to be held about May 31 next, but the list as sent to us by the Secretary, Mr. S. D. Chalmers, is confessedly not yet complete. Mr. Chalmers, who has already several times shown

his personal interest in photographic optics since he accepted the directorship of the Optical Department at the Northampton Institute, will be glad to hear from anyone interested in the subjects with which the Convention will occupy itself. Among the papers at present announced are:—"Some Properties of Lens Systems," by H. Dennis Taylor; "Some Problems relating to Optical Glass," by Walter Rosenhain; introduction to a discussion on aberrations, by Dr. C. V. Drysdale and S. D. Chalmers; "Diffraction in Optical Instruments," by J. Gordon; and "Lens-testing Bench," by H. Beck.

Mercury Vapour Poisoning.

To be set against the many advantages of the new mercury-vapour lamps there is one fact which is not particularly pleasant to contemplate. In the event of a tube breaking there will be a discharge of the highly poisonous mercury vapour, and it is not difficult to imagine conditions in which such an accident might be the cause of death. There is no need for fearing fracture of the tube save by the collapse of the installation or other accident to which any piece of glass apparatus is liable, but the intensely poisonous character of the source of light should prompt the photographer to take more than usual precaution in having the lamps fixed.

A Preventive of Mercury Poisoning.

We may mention here, although the information cannot be advanced as of any practical service, the remarkable power of finely divided aluminium of absorbing vapour of metallic mercury. The fact has recently been applied by a Spanish chemist, N. Tarugi, to the manufacture of a respirator which has been introduced with good results into the mercury mines of Monte Amiata. It is found that mercury vapour, when largely diluted with air no less than the dense vapour evolved by heated mercuric chloride is completely arrested by the spongy aluminium. We would not seriously suggest that the photographer must safeguard himself by habitually donning an aluminium gag, but occasions may arise when such precautionary measures are advisable—and possible.

The Spectre of the Brocken.

In the current number of the "Photographische Korrespondenz" is given a half-tone reproduction of an extremely successful photograph of the well-known phenomenon, the spectre of the Brocken, taken by Herr K. Heller. This, as is well known, is the projection of the shadow of a person on a cloud or mist, produced by the sun being behind the person, and it is usual for the person's head to appear surrounded by three or four concentric coloured rings, or rainbows. In the reproduction it is possible to see not only Herr Heller but also the camera shadow. The negative was obtained with a medium yellow screen and an orthochromatic plate with one second's exposure.

with F 62. We believe that this is the first time that this phenomenon has been photographed.

Cash Prize Competitions.

The competitions organised from time to time by various well-known makers of photographic materials appear to not only meet with a highly gratifying measure of success, but may be regarded as forming an undoubted indication of the widespread interest taken in photography. This is evidenced by the recent "Barnet" competition, the awards in which are published on another page. No less than 10,000 entries from all parts of the world formed the response to Messrs. Elliott and Sons' offer of £500 for photographs produced with their plates and papers. An analysis of the awards shows that several of the competitors secure sums of money ranging from £15 to £30. Prizes worth winning, forsooth. An even larger amount is now on offer in Ilford Limited's competition, which closes on the 31st of this month. No less than £750 in cash is offered in prizes to users of Ilford plates and papers, etc.; 116 prizes amounting to £380 are for professionals only; £282 10s. is set aside for distribution to amateurs in 136 prizes; and £87 10s. will be divided into 130 prizes for junior amateurs. This generous scheme for the reward of their supporters should bring in an enormous return to the Ilford firm. Particulars of the competitions will be sent post free from Ilford Limited, Ilford, London, E.

The Free Portrait Dodge.

Our contemporary "Truth," which has done so much to show up the notorious Tanqueray, states that a rival has arisen in Paris under the name of the Société Franco-Américaine, of which one Saenger is the director, while it boasts of a "Chief of the Artistic Department" in the person of William Hildebrand, Academic Painter. This concern appears to be very active at present in South Africa, from which country the information about it comes. It is true, of course, that Saenger might easily be Tanqueray under a new name, but respect for the inventor and "boss" of the free portrait swindle prevents the supposition that this is so, for the clap-trap of the Société Franco-Américaine is but a shoddy imitation of Tanqueray's highly-finished bunkum. In proof of this, one of Saenger's reproductions of testimonials received from his delighted customers is given:—

"Sir G. A. Finch, Right Honourable M.P.

"Burley-on-the-Hill, Oakham (Rutland),

"sept. 17th 1904.

"Mrs. Finch who sent a photograph of her in Mr. Finch's name is so pleased with the picture which is a very good copy of the photograph. She is sending the coupons to her friends.—Yours faithfully

"This is one of the numerous testimonials sent to us daily and which will be printed in a few days."

A Rule for Exhibition Judges.

At the annual general meeting of the Hackney Photographic Society, reported elsewhere, a proposition was put forward that should prove of interest not only to all photographic societies that hold exhibitions, but also to exhibition judges. The following addition to the rules was proposed: "At any future photographic exhibition of the Society, the judges be furnished with the number and title of the pictures only, the names of the exhibitors being withheld till the awards have been made." The opinions of the members, who include many well-known exhibitors, on this subject, were markedly different in the discussion that followed, and the final decision was to refer the matter to the Council rather than add anything to the rules. We have always been under the impression that it was an unwritten law that

the judges at an exhibition were not made acquainted with the identity of the exhibitors until after they had made their awards. We understand this is always the case when judging the Royal Photographic Society's exhibitions, and that it is the usual custom at most provincial societies, to paste a strip of paper over the names of the exhibitors in the copies of the catalogue given to the judges. If, however, the proposition made at the Hackney Society becomes a precedent for a rule when drawing up the regulations of photographic exhibitions, it will be well to consider two points at least in connection with the judges' knowledge of the exhibitors. The first, and probably most important, is, that under existing conditions the addition of the exhibitor's name to the front of the picture is permissible, which fact, if made full use of, would, of course, defeat the object of the proposed rule; and the second is that, in many instances, more than one award is made to the same exhibitor in one class when the regulations allow only of one award being made. The knowledge of the exhibitor's identity would obviate this, and the judges would be saved much extra labour in re-judging a class. We shall note with much interest the outcome of the Hackney Society's move in the matter, and observe how it works out in practice.

VIGNETTE PORTRAITS.

It has become fashionable of recent years to decry the vignette, and as far as landscapes are concerned, we think there is plenty of reasons for this; but for portraiture the vignette at times is not only appropriate, but advisable. Nevertheless, there are few, very few, subjects that call for this treatment, and it is the use of vignetting for the wrong pictures that has brought the method into disrepute.

Speaking generally, we would say that ladies and young children are the only appropriate subjects; men, never. Thus, again, the ladies and children should be dressed in light materials; if they are not, the dark dress strongly contrasting with the background, which, of course, is light shading off to white, tends to make this subsidiary feature of more importance than the delicate half-tones of the face. The ideal subject is a beautiful woman or child in white costume, taken against a perfectly white or very light grey ground. The picture will then be all in light tone, with the flesh tones slightly darker than the ground and drapery. The pictorialist will say, perhaps, that this is a poor imitation of a pencil drawing or rough study, and that imitation is not art. With this we would disagree. The camera is capable of being used to any end, and, so long as that end is beautiful or artistic (in these days not always the same), an imaginary or accidental resemblance is no drawback. It might with equal truth be retorted that those of the ditch-water school, addicted to huge patches of ungraded black with infinitesimal amounts of half-tone, are imitating poor, very poor, engravings, though, of a truth, the engraver would not be flattered; he delights just as much as the possessor of the latest anastigmat in reproducing every detail and gradation. So long as the vignetting was used foolishly and indiscriminately, as it was when the "cabinet vignette" was the chief stock-in-trade of the professional, the crusade was just—even laudable; but having made their point, and having exterminated the vignette from all but the most backward of professionals' specimens, it is time for the critics to stay their hands and welcome a sensible resurrection of this dainty style.

In our opinion, a certain public must very soon get tired of the brilliant dark background effects, and call for something more light and more suitable for the delicate and transient charms of youth and fashion. Since fashions,

we are told, always travel in cycles, the vignette is certain to be again welcomed, but this time professionals, from their greater knowledge of art, will not perpetrate the monstrosities that drew forth the ire of the cultivated only some ten years ago.

"Drapes," to use an American term, are very useful for vignette busts, and to the uninitiated we may say that a "drape" is some light, soft, filmy material kept to drape the shoulders of those not provided with suitable bodices, also for somewhat ethereal-looking portraits of children. The reader must have seen how extensively this handy material is being used by the London professionals. The usual form is merely a couple of yards of "chiffon," usually cream, and it can be used as the operator may prefer. A "fichu," to borrow another ladies' word, is also requisitioned; it is of the same material, but is made up and usually is provided with a frill or two.

The background now claims attention, and it was here as much as in the selection of subjects that the old exponents of vignetting made mistakes. The ground must be light, for, although a dark ground may be vignetted by a skilful printer, yet they never look well. A perfectly white ground is best. Next best, perhaps, is a grey so skilfully chosen that, though darker than white drapery, it is lighter than the flesh tones. Needless to say, such a ground is somewhat difficult to get. The ground must, at any rate, not be much darker than that if a successful sketchy result is to be obtained.

The great objection to the best ground, the white, is

the difficulty of operating so that the delicate flesh tints and drapery detail are retained on the light side of the model. A very little practice and common-sense arrangement of the light will soon obviate any difficulty. The light must be well ahead of the sitter, none coming from the side for at least six feet in front. We prefer to have the light coming from a large square space directly beside the camera, with the latter, say, six feet from the light. Measuring from the side light, the sitter should then be twelve feet into the room. If the sitting is for a bust and one has an uncovered shoulder which must have modelling retained, we use practically no side light.

These rough guides should be sufficient data for successful use of the white ground. This lighting not only has the effect of keeping modelling on the side nearest to the light, but has the equally desirable effect of giving perfect roundness to the face, with no deep shadow that would be out of keeping with the general scheme.

Developing is, of course, as usual, though care is necessary to stop before one smothers any high lights in the background. The actual vignetting of these prints is the very easiest job that could fall to the printer's lot, little or no skill being required. Practically an old piece of card with hole cut to shape will do, even serrating the edges is not actually necessary. The easiest vignettes to make, in our opinion, however, do not have serrated edges, but holes are punched with a "leather punch" as close to the edge of vignette and each other as possible; this makes a very soft vignette, even with dark grounds.

FINISHING ENLARGEMENTS WITH PASTEL AND BRUSH.

In a previous article I dealt with a method of retouching bromide enlargements with pastel, which is characterised by speed combined with effectiveness, and although it is undoubtedly the best method of finishing for the majority of photographers to employ, there remain one or two others about which it may not be amiss to say a few words.

Probably the next most popular method of finishing is with the aid of the aerograph, which is undoubtedly most useful, and best in all cases when smooth paper has been used, or if the portrait is upon opal or celluloid. The working of the aerograph is readily learnt, and when once the instrument is ready for use the work is rapid enough; but inasmuch as the company which manufacture it are always willing to train purchasers in its use, it is superfluous to occupy space here with directions concerning it.

Another method of finishing is by using sable brushes alone, the work being applied either with hatching or stippling touches. Next to the aerograph, it is the most satisfactory way of retouching opal enlargements; but, inasmuch as it is very slow, it is inferior to the pastel, or combined pastel and brush, finishing of paper ones. In this latter method the work is commenced in pastel, the background, draperies, hair, etc., being principally attended to, as described on page 24 (January 13) of this present volume; but instead of finishing with pencil and stump, brush and colour are substituted, the effect being that of an enlargement from a perfect negative finished by brush-work alone.

Method of Applying Brush-work.

Using water-colour which accurately matches the tone of the enlargement, a sable brush is very sparsely charged with same (it should be almost dry—washes of colour, of course, being quite out of the question). It is then applied to the picture with hatching strokes, or, if preferred, the slower stippling touches.

And for the benefit of the learner it may be as well to state that hatching consists of marks or lines which generally cross one another at a more or less acute angle, whilst stippling consists of dots (made with the point of the brush) instead of lines.

Of hatching strokes there are a variety of forms, and in some of them the lines do not cross one another. One of these consists of zig-zag lines disjointed at their angles, and running horizontally, obliquely, or vertically across the picture, forming a very effective stroke for running over large backgrounds, especially if they are vignetted.

When it is necessary to cover large spaces the strokes should be light, broad, and well scattered. If they are over accessories or draperies they may take the usual direction obliquely downwards from right to left. First make a series of short strokes over the part to be covered at an angle, say, of 45 deg. with the horizontal or sight-line, and then cross these with short lines running about 55 deg. The more they are separated from one another the lighter will be the tone produced, and, conversely, the closer together they run the darker the effect.

When hatching over the flesh it is usually better to let the direction of the strokes follow the form of the features, using fine, curved, over-lapping strokes. Many artists prefer to stipple over the face entirely, and there can be no objection to doing so if there is sufficient time, for, as with retouching, stippling is slower, but produces a finer grain. There is also a form of hatch and stipple touch which gives a nice effect. It consists of oblong dots made with touches of the brush-point, combined with a slightly downward movement, the tails of the dots being downwards.

Again, as finishing a bromide enlargement is similar to retouching a negative, any of the various touches employed for the latter may be made with the brush on the former, the chief points to remember being to have the brush fairly dry, lightly charged

with colour, and to sit well back from the work, for unless this latter matter is observed, the work will certainly have a dirty and unfinished appearance. Of course, in working up the hair, brows, etc., no other definite form of stroke will be employed than that necessary for the mere evening-up or modelling of the part, as hatching over these parts usually produces an artificial look altogether.

For the development of heavy shadows the brush may be more fully charged with colour, but the necessity of keeping it fairly dry must be fully observed.

After the artist has severally attended to the various parts needing touching, a general survey of the whole will usually discover a few imperfections owing to the more or less finishing of part by part. With a little practice, however, it is easy to "pull the work together" with a very few strokes. Do not put on a lot of unnecessary work; not only is it a waste of labour, but the truthfulness of the reproduction will be seriously endangered. It is best to make a habit of endeavouring not to make one unnecessary stroke, experience alone teaching how to make every touch tell.

ARTHUR WHITING.

THE WEEK IN HISTORY.

Beginnings of Dry-Plate Photography.

THE wet collodion process of Archer, introduced in 1851, was not very long in use before the first signs of reaction to a dry method commenced to be apparent. Thus in 1853 we find M. A. Girod, in "La Lumière" of March 19, explaining that he lays a second glass plate on the one he has collodionised and sensitised. Thus protected, the sensitive plate may be kept for a day before exposure. Though M. Girod writes positively that the collodion film sustains no damage in the interim between sensitising and development, his method was an obvious *tour de force* outside the limits of practical photography. A few weeks later, in "La Lumière," M. Gaudin recommended separating the two plates round their edges with strips of blotting paper, and also carrying the plates in a grooved box, thus hindering the evaporation of moisture from the film. But these plans, cumbrous in themselves, doubled and trebled the weight of the sensitive plates, and the day of the dry plate was brought in, not by them, but by the chemical advances which rendered possible, first the dry-collodion and collodion-emulsion plate, and then the gelatine emulsion.

Toning without Gold.

I cannot assign a date to the introduction into photography of a process for obtaining a dark or black tone on paper prints without the aid of gold or other of the precious metals. Gold toning commenced with Daguerreotype, and was modified in numerous ways to fit the various processes as they arose, but toning without gold, that will-o'-the-wisp which has laid waste the labours of many photographers, apparently grew gradually out of the practice of calotype workers to employ an old or highly worked fixing bath for toning purposes. The

action which took place was probably nothing more than "sulphur toning," as we now apply the term and the operation to bromide work for warm tones, but, whereas a "sulphur-toned" bromide has some reasonable claims to permanency, old print-out papers when treated in this manner gave an image not only of silver sulphide, but containing other sulphide compounds which speedily altered in the light and ruined the print. Quite a different process, however, is forty-five years old on Tuesday next, March 21, it having been patented in 1860 by two Americans, J. C. Rutherford and B. H. Steele. The toning bath, which presumably was to be applied to prints on plain paper, is specified in the patent (No. 735) as follows:—A mixture is made of corrosive sublimate, tartaric acid, sal soda, hydrochloric acid, and water. It is left standing forty-eight hours, and, after filtering, is ready for use. This fantastic mixture of acids and alkali apparently amounts to tartrate of mercury, and may have been suggested by Sir John Herschel's printing process, in which that material was used. (Hunt's "Researches on Light," 2nd edition, page 160). Herschel found the prints fugitive, but the patentees of the mixture were in no doubt as to the permanency of the toned pictures.

The Liverpool Photographic Society.

There are three photographic societies in Liverpool at the present time, but none of them perpetuates the "Liverpool Photographic Society" founded on March 22, 1853. That society has a special interest for readers of the B.J.P., because the journal which it established a year later became in 1860 the present BRITISH JOURNAL OF PHOTOGRAPHY. But the original Liverpool Photographic Society, if I am not mistaken, did not survive the year 1866.

HISTORICUS.

MESSRS. FUERST BROS., 17, Philpot Lane, London, E.C., send us their current list of photographic chemicals.

"THE B.P.S. Journal."—Under this title the monthly programme of the Birmingham Photographic Society is enlarged into a presentable and admirably gotten-up little booklet, and forms the official record of the association. Notes on lectures and demonstrations given at the society's headquarters, Norwich Union Chambers, Congreve Street, Birmingham, particulars of the society, correspondence, and an exchange column—at present blank—help swell the publication to twelve pages and an art green cover. Editorial comments on topics of interest to members are a feature, and they appear under the heading of "Ex Cathedra." We seem, somehow, to have observed this title somewhere else in print, but no matter. This energetic and flourishing Midland society is to be congratulated on a production which exudes the secretarial balm of esprit de corps from every page.

SPEAKING Postcards.—The subject of phonographic postcards, as likely to oust the popular picture postcard, forms the topic of humorous comment in an editorial of "The Express." The opinion is offered that "if you call a man a chuckle-headed son of a sea-cook on a postcard or ask how much he got for the umbrella he took out of your hall, you are liable to be cast in damages for libel, no matter how illegible your handwriting. At the end of the present month you will be able to say the same thing or sing it to a Gregorian chant into a gramophone and send the resultant disc to your friend without coming within the peril of the law—at least, so we suppose. Gramophone discs capable of being struck on an ordinary postcard and sold for sixpence will by that time, we are assured, be on the market. What need henceforth even the lovers' meetings? Amaryllys will have naught to do but place her gramophone on the stool at her feet and hear her lover swear in the throaty voice peculiar to lovers and gramophones. Creditors likewise will hear their debtors swear, but in a different language."

THE AMIDOL DEVELOPER.

THE notable developing property of amidol, especially its strong reducing action in the absence of an alkali, has led to its being widely adopted. In spite of the ease with which this developer can be mixed just before use, it is not so generally employed as one might assume, because it loses its developing power fairly quickly.* We have undertaken to determine the causes of the changes of the amidol developer, and to find means to preserve its developing power.

Up to the present it has been believed that the most important cause lies in the ease with which dilute solutions of amidol absorb oxygen from the air. We may, in fact, assume that the developer, in which the sodium sulphite plays the part of alkali, loses its developing power from the moment in which the substance which acts as an alkali no longer possesses this property. One may also assume that the first yellow, later brown, and finally red colouration which the solution acquires in proportion to the diminution of reducing power is to be ascribed to the increasing oxidation of the amidol on account of the destruction of the sodium sulphite.

The True Cause of the Trouble.

We have determined that these generally accepted hypotheses are erroneous, and that the alteration of the amidol developer does not rest on the destruction of the sodium sulphite, but on the oxidation of the amidol by the air, and which is only delayed but not prevented by the presence of the sulphite.

In fact, if the quantity of sodium sulphite is determined which a normal amidol developer of the composition here given contains,

Amidol	5 g.
Anhydrous sodium sulphite	30 g.
Water	1,000 ccs.

when it has lost all its reducing properties and the solution is a deep red, it will be found that it still contains 75 per cent. of the original quantity of sulphite, a quantity which is absolutely sufficient to give to a freshly mixed developer a developing power which is very near that of the normal developer.

It will be found on the other hand, that when more sodium sulphite is added to the inactive solution its developing property is not increased to any extent, whilst the developer will attain its original power if the original quantity of hydrochlorate of diaminodiphenol (amidol) is added. It appears, therefore, that the loss of the developing power is caused by the destruction of the amidol.

In order to determine whether this destruction is caused by absorption of atmospheric oxygen, a litre flask was filled with normal developer, tightly corked, and paraffined, and left for about a year. We were able to determine that under these conditions the developer only turned a faint yellow colour, and that its reducing power had not decreased to any extent after being kept so long.

The change in an amidol developer in an uncorked bottle may be considerably retarded by covering it with a film of ligroin or petroleum, which prevents the access of the air. It is therefore the oxygen in the air which causes the change.

The Influence of the Quantity of Sulphite.

As sodium sulphite considerably retards the oxidation of the hydrochlorate of diaminodiphenol, we have investigated whether the keeping power could not be increased by increase of the quantity of sulphite in the developer. For this purpose the keeping property of a normal

developer was compared with that of solutions in which the quantity of amidol was normal, but that of the sulphite was both reduced and increased. The solutions contained 5 grammes of amidol per litre, and the following quantities of anhydrous sodium sulphite:—

No. 1.—Amidol solution without sulphite.	
No. 2.—Amidol solution with 1 gramme sulphite.	
No. 3.— " " " 2 " "	
No. 4.— " " " 5 " "	
No. 5.— " " " 10 " "	
No. 6.— " " " 15 " "	
No. 7.— " " " 30 " "	
No. 8.— " " " 50 " "	
No. 9.— " " " 75 " "	
No. 10.— " " " 100 " "	
No. 11.— " " " 150 " "	
No. 12.— " " " 200 " "	
No. 13.— " " " 250 " "	

The solutions were kept in uncorked flasks at the same temperature. It was determined that the solutions which contained up to 3 per cent. of sulphite darkened less quickly the less sulphite they contained, but above this proportion the discoloration was, in the same time, the more intense the more sulphite was present. In solution No. 13, which is saturated, the discoloration increased more rapidly than with all the others; it was weaker and weaker from the surface of the solution to the bottom, from which it is obvious that the absorption of oxygen at the surface took place much quicker than the diffusion of the oxidised solution into the underlying liquid. If the alteration of the amidol developer is to be ascribed to the oxidation of the sulphite one must have observed the opposite; as the solutions which were richer in sulphite would oxidise more slowly. We have in fact proved in a previous paper that solution of sodium sulphite absorbs oxygen from the air more slowly the more concentrated it is.†

Keeping Concentrated Solutions of Amidol and Sulphite.

We have tried the possibility of increasing the stability of the amidol developer by simultaneously increasing the proportion of amidol and sulphite. For this purpose, to a saturated solution of anhydrous sulphite, 250 grammes to the litre, the corresponding quantity of amidol, 40 grammes, was added, so that a normal developer would be obtained when the concentrated solution was diluted with seven volumes of water.

Under these conditions the solution blackened, even in well-corked bottles, quicker than a normal developer under the same conditions, and there was formed in a short time at the bottom a brown crystalline precipitate, which slowly increased. It is easy to explain why solutions with equal proportion of amidol should oxidise more quickly in the air the richer they are in sulphite. One may in fact assume that the sulphite is first used to set free the base of the hydrochlorate of diaminodiphenol, according to the following equation:—

* As the rapidity of the loss of the developing power varies with the temperature, it is impossible to accurately determine the time in which a normal amidol developer becomes useless. Still it may be experimentally determined that when the developer is kept in a half filled litre bottle, without a cork, at about a temperature of 17 deg. C., the developing power gradually decreases, until in about twenty days it is nil.

Calculating from this equation, 6.3 grammes of anhydrous sodium sulphite are required for 5 grammes of diamidophenol hydrochlorate in each litre. When the sulphite surpasses this theoretical quantity, one must take into consideration the reducing power of this salt, and the alkaline reaction which it imparts to the solution and which increases with the increase of the quantity. As alkalinity considerably assists the oxidation of the phenols and amines, it is probable that the reaction of the reducing power is kept in equilibrium by a certain ratio of sulphite to the amidol solution.

On the other hand the diminution of the reducing power of concentrated amidol solution in saturated sulphite solution, in which in full corked bottles a copious brown crystalline precipitate appears, may be explained by the fact that the diamido phenol, the base, is very slightly soluble in saturated sulphite solution. One may assume that this very variable substance is precipitated, and thus the reducing power of the solution is considerably lowered.

Conclusions.

We may therefore draw the following conclusions from the above statements:—

1. The alteration of the amidol developer is not to be ascribed to the oxidation of the sodium sulphite, but to the oxidation of the amidol, as the sulphite is much less oxidised in the presence of sulphite than in a simple aqueous solution.

2. An excess of sulphite over the normal quantity in the developer does not retard the oxidation of the amidol; indeed it rather accelerates it.

3. The solutions saturated both with amidol and sulphite oxidise more readily than the normal solutions, and cannot be kept even in well-corked bottles on account of the precipitation of the amidol.

4. On the contrary the normal developer may be kept without marked change in a full well-corked bottle for a long time.

A. and L. LUMIERE and A. SEYEWETZ.

LANTERN MANIPULATION.

LANTERN manipulation is an undoubtedly large subject, appealing not only to the professional lanternist, but more particularly to photographic societies, whose evening lectures and demonstrations largely depend on the successful working of the society's lantern. It will be generally found that in the absence of the hon. lanternist there is generally a great dearth of members who are willing and able to undertake his duties, and carry through their part of the evening's entertainment without a hitch. Mr. W. H. Smith, president of the Croydon Camera Club, in a lecture to the members of that association last week, dealt very fully with the subject in a manner that should make clear to the amateur lanternist many points of difficulty that are likely to occur when using the lantern and oxy-hydrogen jet.

Oxygen Cylinders.

The lecturer dealt first with the jet. He said that the jet known as the "blow through" is almost universally used by amateurs, and would alone be considered. With this jet, the oxygen gas only is required under pressure. The hydrogen being represented by the gas supply from the mains. Oxygen is now readily obtainable in nearly all localities in steel cylinders, compressed to 120 atmospheres, which is a convenient method of storage, inexpensive, and, above all, safe; as the cylinders are periodically tested at a pressure greatly in excess of the actual working one, and re-annealed at fixed intervals. There can be but little doubt that if lanternists all made their own gas the percentage of accidents would be considerable indeed. The gas is supplied in cylinders of almost any capacity, but for lantern work, cylinders of from 6 to 20 cubic feet are most convenient. Ten cubic feet will be found ample for a two hours' entertainment; and, as a matter of fact, with care and a good jet, 6 cubic feet would be sufficient for any ordinary lecture. Owing to the pressure at which the oxygen is stored, viz., about 1,800 lb. to the square inch, it would not be possible to turn the gas down at the jet without the rubber tubing and fittings giving way; and, this being so, it is almost compulsory to use a regulator or reducing valve, which will deliver the gas at a convenient pressure—about 2 lb. per square inch is found suitable in practice.

The Regulator.

The first thing we have to see is, naturally, that a supply of oxygen is at hand, we can then turn our attention to the regulator to ascertain if it is in proper working condition. This must be screwed on

to the cylinder; if we have any experienced friend to show us how this is done, well and good, if not, by carefully following the instructions of the makers (which will be sent on request) no difficulty should be experienced. The regulator having been satisfactorily adjusted, the outlet should be stopped; a finger-tip is generally utilised for the purpose. The jet can now be turned on at the cylinder, about one quarter turn being quite sufficient. If, on listening, no sound of escaping gas is heard, the regulator may be considered in proper working order. The valve is forthwith closed, and the cylinder placed on one side for the time being. The cylinder valves should be closed tightly, but not forced, as any undue pressure is apt to destroy the plug seating. The same remark also applies to the regulator.

Making Ready the Lantern.

Assuming the ordinary supply of coal gas to be available, and knowing the limes are in good condition, viz., perfectly dry and unbroken, we can proceed to set up the lantern. When erected, note that the condenser and projection lens are clean; if dirty, take them apart, and, with a soft clean piece of material, carefully wipe each surface, taking care to replace the parts in their correct position. It is very easy for an inexperienced hand to wrongly re-insert the components, unless attention is paid in the first instance. We next see to the gas connections. The oxygen tap of jet is generally marked, but, if not, it can be easily traced, being fitted on to the tube, terminating at one end centrally in the jet. When connecting the rubber tubes to the jet and sources of gas supply, take care that good joints are made, especially to the regulator, or much of the oxygen may be wasted. The tube connections to the cylinder must be free from dust or coal gas, and, if the tubing be new, it should be washed before use. These are by no means needless precautions.

Everything being so far satisfactory, we now place a lime cylinder on the pin provided for the purpose. The lime, it will be seen, has a small hole bored through; frequently this hole is too small, or is full of dust. In either case it must be cleared, and for this purpose a bradawl is as good as anything. The lime must fit the pin quite freely, but not too loosely, any adherent dust being blown or brushed off. Its correct position is about $\frac{1}{4}$ in. from the nozzle of the jet.

Adjusting the Gases.

The coal gas may next be turned on and lighted, with enough flame to well lap the lime, the jet at the same time being drawn an inch or two back from the condenser. In order to warm the lime

equally, it should be slowly rotated for a minute or two, and left with the flame on it. If possible, this preliminary lighting up should be done about half an hour before the lantern is required for use. Meanwhile the screen can be fixed, the slides wiped, and deposited in a warm place. If there is a fire or stove handy, they may advantageously be placed in front. With the lantern, slides, projection lens, and condenser well warmed there should be no trouble with condensation, the *bête noir* of the lanternist, and the risk of cracking the condenser is minimised. All being ready, the lantern can be placed at the right distance from the screen for focussing adjustment. First note that the oxygen tap on jet is closed, and turn the gas on at the cylinder; next turn on a little oxygen at the jet tap, then a little more coal gas, and so on, until the most brilliant light is obtained.

Obtaining the Best Light.

Should there be too much oxygen, then a small black spot will appear on the lime, due to a cooling effect. This can be conveniently observed by its reflection from the back surface of the condenser. If apparent, try turning on more coal gas, which may cause it to disappear, if not, the oxygen must be reduced. A little practice is all that is required, but it will be found that a slight excess of coal gas is necessary. There should be no noise at the jet, which signifies waste and less light. Directly the light is good—it need not be at its best for the moment—insert a slide in the lantern, and adjust the jet roughly. There is no need to trouble about even illumination at this stage, so long as some light gets through on to the screen. Focus sharply, and withdraw slide. The circle of light

will probably be found very uneven, but by shifting the jet backwards or forwards, and up and down, the best position is soon found.

The lantern may now be considered ready for use, and will give no further trouble. If not required at once, the oxygen tap should be shut off at the cylinder and the coal gas reduced a minute or two sufficing to get everything working again.

Points to Remember

In conclusion, there are a few other matters which should receive attention while the lantern is running, the observance of which makes all the difference between a good and a bad lanternist. In the first place, it must not be forgotten to turn the limes occasionally; the heat from the mixed gases is very great, and burns hollow places in the limes, and these depressions or pits sometimes divert the flame on to the condenser, with disastrous results. When a lime is being turned, the light is momentarily reduced, do not, therefore, fall into a common error of performing this operation whilst a slide is being shown—it is best effected when a slide is being changed, then the diminution of light is hardly noticeable. Be careful, also, to drop the slides into the carrier without unnecessary noise, and to withdraw them without shaking the following slide. Focussing should be done rapidly, but the movement of the lens should not be extended so far in either direction as to transform the image on the screen into a pronounced "fuzzy-type," which would have a distressing effect on the eyes. To ensure nice focussing, the lens must slide sweetly in its socket, a condition of affairs which, in the commercial lantern, does not always exist.

THE CAPACITY OF DIFFERENT PRINTING PROCESSES FOR RENDERING GRADATION.

II.

Comparison of Negatives.

As it seemed improbable that negatives would contain anything like such extreme gradations as those mentioned in the first portion of this paper (see last week's "B.J."), I proceeded to test the gradations of some of my own, the test being the same as before, viz., finding the exposures required to give an equal tint to the deepest shadow and the highest light which would be required to print. It seems needless to consider the *extreme* opacity to be found in the negative, as there may be a patch out of all relation to the rest of the negative and which could never be required to print. I therefore considered as the highest light that which would show on a P.O.P. print as a slight tint before toning and as pure white after the print was finished. In the negatives which I have made in recent years, using amidol as the developer, I find a range of opacity of about 1 to 40 or 50 very common in landscape subjects, and I show you one which I consider a fair average printer which has a range of 1 to 40. Others of the still-life kind seem to run rather higher. One I show you has opacities 1 to 100, and another of 1 to 150. Going back to the negatives I made in the days of pyro-ammonia and albumenised paper, I find a much greater contrast. The example I show has contrast from 1 to 350, partly due to pyro-stain. Later on you will see that negatives of the class we produced twenty years ago are very unsuitable for some of the modern printing materials. Of course, the introduction of so many soft-working developers has produced quite a different type of negative, and manufacturers turn out their papers to suit the new conditions.

Now let us see what degree of contrast the different processes are capable of rendering effectively.

Printing-out Papers.

naturally claim first attention. I show you a number of prints taken from my graduated screens on different makes of P.O.P., some well known, others less so. It would be absurd to say that one paper is good and another bad. All are good for some particular kind of negative, and no really bad paper could possibly remain on the market. Many of you, however, will probably be surprised to find so much difference in the printing capacities of even gelatine P.O.P.

Amongst all the printing processes now at the command of photographers, those which give a fully visible image in the printing frame undoubtedly remain most popular, especially those gelatino- or collodio-chloride papers familiarly known as P.O.P. They are all capable of rendering a fairly long range of gradation, but amongst the various examples I have tried it is noticeable that one kind differs from another, sometimes to a considerable extent, and that even the less enterprising photographer, who shuns carbon or platinum because he "likes to see what he is doing," will find some advantage in using more than one make of P.O.P. They differ in the extent of gradation they register, ranging between 1 to 15 and 1 to 20 tints on my screen, representing opacities of 1 to 64 and 1 to 256. That means that a negative possessing a large range of contrast may have all its tones registered on a paper of the latter class, while on the former class there must be blocking up of shadows or loss of detail in lights with such a negative.

Depth of Colour a Factor in P.O.P.

A still more important difference, however, lies in the *steepness* of the gradation. Two papers may be found which register exactly the same number of gradations, but the depth of colour attained in the deepest shadows may be very much greater in one than in the other. The discoloration due to one unit of light and twice that unit is not the same in all papers, and the difference may be illustrated by two flights of stairs, one having higher steps than the other, so that one rises to a greater height than the other for a given number of steps. These two papers will give prints of a different character from any negative. If the negative contains the same gradations as the paper is capable of rendering, the steeper paper will give the most "brilliant" print, but both prints will be good each in its own way. If, however, the negative is flat, and *within* the scale of the paper, the steeper paper will give the better print. On the other hand, of course, the softer paper will best render a harsh, over-developed negative, because the shadows will be lighter in tone, although they will contain no more detail; in other words, the print will be softer.

Gradations in P.O.P. not Correct.

The gradation in all printing-out papers presents a certain important peculiarity. Examination shows that, in all the examples prepared, there is a gradual decrease in the steepness of gradation towards the shadow end, which becomes very marked in the deeper tones, where the difference between any two contiguous exposures becomes hardly perceptible. The explanation is simple. As the silver compounds darken during printing, the discoloured particles act as a screen to those lying beneath them, so that the darkening of the latter is delayed. The greater the amount of darkening, the greater the screening effect; hence the lighter of two tones tends to overtake its darker neighbour, and the contrast between them is less than the contrast between the corresponding tones of the negative used. The effect of this is to soften the shadows of the print and lengthen the scale of gradation, as will be seen by comparison with other classes of papers where this screening effect does not arise. At the other end of the scale there is also a somewhat abrupt falling off in the gradation not quite so easily explained. It will be noticed that the gradations *print out* clearly enough, but that they disappear, or are disproportionately reduced during toning and fixing. I ascribe the loss of these delicate tones to the fact that silver chloride prints out more rapidly than the organic silver compounds which are associated with it, and which give richness and depth of colour to the print, hence the lighter tones consist mainly of chloride alone, which is more reduced during toning and fixing than the organic compounds. This seems the more likely, because I have noticed that in these experimental prints the lightest tones—those which suffer most in the after processes—are, when taken from the printing frame, distinctly bluer in colour than the somewhat darker tones adjoining. The conclusion is therefore inevitable that printing-out papers cannot possibly give a correct rendering of the negative, although their vast popularity indicates that they give a rendering which pleases the majority of photographers. No doubt the softening in the shadows is rather welcome than otherwise, while the abnormal gradation at the other end of the scale gives a certain sparkle or brilliancy which is equally desired.

Assisting Detail and Shadows.

The strength of the light in P.O.P. printing does not seem to affect the total range of gradation much, but it does affect its character. Printing in the sun considerably strengthens the detail in the lights. It seems that the stronger light causes the earlier formation of the organic compounds which I have already spoken of, so that the abrupt falling off in fine detail, due to the absence of these compounds, does not take place, hence the advice to print dense negatives in the sun is sound.

The surface of the paper has considerable influence on the rendering

of gradation. It appears that when the colouring matter is spread throughout a comparatively thick layer of transparent medium such as gelatine there is a depth and transparency which is lacking when the particles are crowded into a thin layer. No doubt the gelatine acts as a varnish, preventing the surface reflections which rob the shadows of depth when the surface is "matt." Enamelling still further improves the depth of shadows and enables minute differences of shadow gradation to show themselves, which would be invisible even with the natural gloss of the paper.

There is a P.O.P. paper of foreign manufacture designed for printing negatives of very small range of gradation. It evidently contains a yellow dye, to which its peculiarity is due, and is made in several degrees of hardness. I do not know which degree the sample I have tried represents, but it gives a range of 1 to 12, thus equalling some of the gaslight papers.

The Carbon Process.

Closely allied to P.O.P. we have the processes of printing in pigmented gelatine, to which the general term carbon printing is applied. It is a peculiarity of this process that its range of gradation is variable at will, over fairly wide limits, by varying the strength of the sensitising bath. An average bath of 4 to 5 per cent. of bichromate will give a range about the same as the majority of the P.O.P.'s, but for such a gradation a negative of a considerable range of opacities is needed to bring out the full value of the rich deep shadows which are characteristic of the process. If, however, the tissue is sensitised on a bath more diluted, the range of gradation is shortened and rendered much steeper, and the negative may be correspondingly thinner. On the other hand, tissue to suit a negative of extreme contrast may be prepared by sensitising on a bath of greater strength up to about 8 per cent. Beyond that strength trouble arises owing to crystallisation of the bichromate in the film, and even at 8 per cent. I have noticed signs of it.

The Sensitising Bath and Gradation.

The gradations I have obtained are:—

8 per cent. bath	1 to 64
4 per cent. bath	1 to 32
1 per cent. bath	1 to 16
$\frac{1}{2}$ per cent. bath	1 to 8

But these show carbon at its worst, as they refer to tissue twelve hours after sensitising.

I regret that I have been prevented from finishing my experiments with this process, but it is known that its range of gradation increases with keeping, and it is usually supposed to be at its best about four days old, when it probably is about equal to P.O.P.

The Effect of Keeping.

Since writing the above I have made further experiments, and find that after keeping the sensitised tissue five days, the scale increases approximately as follows:—

8 per cent. bath	1 to 96
4 per cent. bath	1 to 48
1 per cent. bath	1 to 24
$\frac{1}{2}$ per cent. bath	1 to 12

And after ten days:—

8 per cent. bath	1 to 128
4 per cent. bath	1 to 64
1 per cent. bath	1 to 32
$\frac{1}{2}$ per cent. bath	1 to 16

The tissue was kept in an air-tight tin, and the temperature did not exceed 45 deg. during the period of keeping.

In warmer weather it would probably "ripen" more rapidly. It is important, therefore, in controlling results with carbon, to pay attention to the age of the tissue as well as the strength of the bath.

WILLIAM GOODWIN.

[The conclusion of this paper is to follow.—Eds., B.J.P.]

THE BARNET COMPETITION.

£500 in prizes and 10,000 entries.—Those are the two outstanding facts of the great enterprise which Messrs. Elliott and Sons, Ltd., completed last week. That such an assemblage of photographic work should be brought together from all parts of the world under the aegis of one firm of manufacturers is evidence not only of the popularity of its products, but also of the solidarity of photography as a pastime for the million. Messrs. Elliott spread their nets for the amateur and the collection of pictures, which a representative of THE BRITISH JOURNAL OF PHOTOGRAPHY inspected at Barnet, includes the work of a notable proportion of the best-known people. That fact should particularly gratify the promoters of the competition, inasmuch as the sensitive materials employed by the prize-winners represent almost every photographic process and method. The preference for Barnet products among a number of skilled and discriminating photographers is not confined to one only of the many different plates and papers of which Messrs. Elliott are the makers. The following is the award list issued by the judges, Messrs. T. Bedding, A. C. Brookes, and A. Horsley Hinton:—

Class 1.—First prize (£10), Herbert Bairstow, Halifax; second prize (£5), W. A. I. Hensler, South Hackney; third prize (£3), E. B. Vignoles, Streatham, Berks; fourth prize (£1), John Hummel, Wandsworth Common. Half-guinea prize-winners.—Harry S. Parsons, Harlesden; H. Everard Winter, Harlesden; Wouter Cool, Rotterdam; W. G. Hill, Eaglescliffe, R.S.O.; A. M. Walters, Tewkesbury; Robert Marshall, Grangemouth; J. Johnson, Kettering; Ernesto Moreschi, Italy; Frank Gregg, Brixton; J. Ludlam, Leicester; Charles Branch, Eastbourne; Charles J. Reade, Wolverhampton; William Allan, Beith, N.B.; C. G. Jones, Manor Park, E.; Frank E. Huson, Streatham.

Class 2.—First prize (£10), J. C. Varty-Smith, Cumberland; second prize (£5), Oscar Hardee, Chislehurst; third prize (£3), W. Fry, Manchester; fourth prize (£1), W. A. I. Hensler, South Hackney. Half-guinea prize-winners.—T. W. Simonson, Sheffield; Miss A. B. Warburg, 8, Porchester Terrace, W.; Thomas L. Winnett, Gravesend; Rev. H. H. Lowe, Kensington, W.; A. H. Blake, Charing Cross Road; E. Hall, Whitby; Dr. Ernest G. Boon, Italy; Auguste Minguet, France; Charles E. Wanless, Scarborough; David Charles Branch, Eastbourne; Charles J. Reade, Wolverhampton; Louis C. Logan, Woking; B. Wiehr, Dresden; James Patrick, Edinburgh; Ellis Kelsey, Eastbourne.

Class 3.—First prize (£10), Charles Kirk, Glasgow; second prize (£5), Miss Kate Smith, Watford; third prize (£3), Herbert Bairstow, Halifax; fourth prize (£1), Mrs. M. Preston Durn, Wotton-under-Edge. Half-guinea prizes.—E. Nogel, Sydney; R. B. Spanswick, St. Albans; W. Kilbey, London; R. Organ, Swansea; W. T. Brass, near Taunton; F. C. Cobb, Margate; A. G. Pike, London; R. Tepe, Holland; W. A. I. Hensler, London; A. W. Sargent, Cardiff; G. H. Stanford, Boscombe; Philip A. Wickeison, London; Mrs. D. Mahony, County Dublin; Frank Herbert Biddle, Birmingham; F. W. Barnes, Sheffield.

Class 4.—First prize (£20), J. C. Richards, Birmingham; second prize (£10), Oscar Hardee, Chislehurst; third prize (£5), David Murray, Wolverhampton. £1 prizes.—W. A. Cadby, Kent; Miss A. M. Walters, Tewkesbury; Herbert Bairstow, Halifax; Stuart E. Neame, Bristol; E. B. Vignoles, Berks; E. H. Blake, London; Mrs. G. A. Barton, Birmingham.

Class 5.—First prize (£10), Charles A. Slatter, Luton; second prize (£5), Dan Dunlop, Motherwell; third prize (£3), E. Seymour, Watford; fourth prize (£1), C. J. King, Scilly. Half-guinea prizes.—Miss D. Dillon, Folkestone; H. A. Briscoe Harrison, Edgbaston; Thomas H. Jenkinson, Hadley; A. E. Burgess, Addlestone; Harry Cross, St. Leonards-on-Sea; George T. Nichols, Peterborough; William Stubbs, Blyth Bridge; George R. Henderson, Hebburn-on-Tyne; Alf. J. Loughton, Southwell; Charles Upton Cooke, Islington, N.; S. G. Kimber, Southampton; Arthur Smith, Nelson; A. W. Cooper, Preston; James Dunlop, Motherwell, N.B.; Albert England, Barnet.

Class 6.—First prize (£10), H. H. Luther, Huddersfield; second prize (£5), A. G. Thistleton, Newton Heath; third prize (£3), J. H. Osborne, Brighton; fourth prize (£1), David Murray, Wolverhampton. Half-guinea prizes.—Arthur Black, Nottingham; W. G. Hill, Eaglescliffe, R.S.O.; W. R. Lathbury, Bristol; Frank W. Gregg, Brixton; John W. Harrison, Middlewich; W. H. Reed, Haddingley; Thomas R. Somerford, Brixton, S.W.; Carslake Winter Wood, Brighton; T. H. Cliffe, Hertford; A. J. Lindford, South Tottenham;

Harrop P. Wight, Newcastle-on-Tyne; Charles J. Reade, Wolverhampton; James Dunlop, Motherwell, N.B.; Albert E. Burnett, Redland; George T. Nichols, Peterborough.

Class 7.—First prize (£10), E. O. Hoppé, London; second prize (£5), Miss Maud Shilling, London; third prize (£3), Miss Winifred Fink, London; fourth prize (£1), John Dunlop, Motherwell, N.B. Half-guinea prizes.—H. Briscoe Harrison, Birmingham; Owen G. Williams, Liverpool; Mrs. Straton, Hertford; James F. Ryan, Fermoyle; William Ferguson, Auchterarder, N.B.; Miss Helen Pollock, Glasgow; S. H. Fry, London; Sam Swinden, Leeds; Wm. Thorburn, Glasgow; Edgar R. Bull, London; Ompond, Orkney; W. Deeley, Enfield; Miss A. Shipway, London.

Class 8.—First prize (£10), H. C. Leat, Bristol; second prize (£5), W. A. Casson, London; third prize (£3), H. A. Briscoe Harrison, Edgbaston; fourth prize (£1), Leonard Marshall, Italy. Half-guinea prizes.—Vico Diem, Trieste; E. S. Baker, jun., Birmingham; T. C. Richards, Penrith; Miss Elsie Ross, Cheshire; E. O. Hoppé, London; James Ompond, Orkney; Lucy Ross, Tain, N.B.; Edgar R. Bull, London; James H. Saunders, Leeds; Sam Swinden, Leeds; Wm. Deeley, Enfield.

Class 9.—First prize (£5), James Shaw, Manchester; second prize (£3), Edgar R. Bull, London; third prize (£2), Paul Mattia, Alger; fourth prize (£1), John W. Ellis, M.B., Liverpool. Half-guinea prizes.—Harry Holt, West Kirby; G. Kimber, Southampton; A. W. Searley, Devon; John B. Anderson, Belfast; Frank W. Gregg, Brixton; W. L. F. Wastell, South Woodford; A. W. Cooper, Preston; Thomas H. Greenall, Chorley; C. Wade, Carnoustie; Alex. Marshall, Weston-super-Mare; C. W. Appleyard, Sale; J. Dencey Whittles, Birmingham; Fred Ashwell, Morley; Amy Heimann, Berlin; Thomas Jackson, Leeds.

Class 10.—First prize (£10), Harry S. Parsons, London; second prize (£5), S. E. Neame, Clifton; third prize (£3), John Smith, Liverpool; fourth prize (£1), A. H. Blake, London. Half-guinea prizes.—Charles E. Wanless, Scarborough; E. Seymour, Watford; Charles H. Cooke, Islington; Fred G. Price, Crumlin; Charles J. Reade, Wolverhampton; H. C. Leat, Bristol; Leonard Marshall, Italy; Oscar Hardee, Chislehurst; J. W. Barnes, Sheffield; Frank Wilkie, Bristol; Miss Elsie Ross, Cheshire; John Hummel, London; James Shaw, Manchester; J. C. Varty-Smith, Penrith; Robert Marshall, Grangemouth.

Class 11.—First prize (£10), Mrs. G. A. Barton, Birmingham; second prize (£5), Stuart Elwin Neame, Clifton; third prize (£3), George T. Nichols, Peterborough; fourth prize (£1), J. Whiteman, Lincoln. Half-guinea prizes.—W. A. Casson, London; Kate Smith, Watford; Mrs. E. W. Girdlestone, Sutton Coldfield; B. J. Mitchell, Frome; Harry W. Witcombe, Maidstone; John Hummel, Wandsworth; Camille Vernet, France; W. Foster Brigham, Scarborough; W. J. Hart, Shettleston; William Brotherton, Barrow in Furness; W. I. F. Wastell, South Woodford; Fred G. Price, Crumlin; A. G. Thistleton, Newton Heath; R. Tepe, Holland; S. G. Kimber, Southampton.

Class 12.—First prize (£10), Mrs. G. A. Barton, Birmingham; second prize (£5), Mrs. Turnbull, Hawick; third prize (£3), H. Sutcliffe, Eccles; fourth prize (£1), E. Seymour, Watford. Half-guinea prizes.—G. A. Fowkes, Duffield; Alf. E. Allen, Saxmundham; E. Till, Dukinfield; Rev. G. Hugo Heynes, Nottingham; H. Aylward Game, London; Thomas J. Croft, Bristol; A. Shelley, Longton; Owen G. Williams, Liverpool; F. C. Pritchard, Hereford; Robert S. Briggs, Darlington; Alfred Hyder, London; V. G. P. Hendriks, Rotterdam; Oliver G. Pike, Winchmore Hill; Albert E. Burnett, Redland; Sam Swinden, Leeds.

Class 13.—First prize (£10), Miss Hilda Stevenson, Birkenhead; second prize (£5), Mrs. G. A. Barton, Birmingham; third prize (£3), Dan Dunlop, Motherwell; fourth prize (£1), Fred Graves, Kenilworth. Half-guinea prizes.—A. J. Lindford, South Tottenham; W. G. Hill, Eaglescliffe, R.S.O.; A. G. Thistleton, Newton Heath; Mrs. E. D. Girdlestone, Sutton Coldfield; Francisco Toda y Namode la Rosa, Madrid; Amy Heimann, Berlin; S. Elwin Neame, Clifton; A. E. Burnett, Bristol; Charles Upton Cooke, Islington, N.; Harrop P. Wright, Gosforth; Mrs. Yates Bainbridge, Newbury; G. M. T. Smyth, Tenby; Herbert Aylward Game, Bayswater; T. Moyser, Streatham, S.W.; Thomas Norman Jenkinson, Hadley.

Class 14.—First prize (£10), J. Cruwys Richards, Bournville; second prize (£5), Henry Light, Birmingham; third prize (£3), A. H. Blake, London; fourth prize (£1), Walter Briggs, Hexham-on-Tyne. Half-guinea prizes.—Thomas R. Somerford, London; Thomas Humphries, Portsmouth; W. Foster Brigham, Scarborough; John Hummel, London; M. Montgomery, New Brighton; A. Nicholson, Roundhay; S. G. Kimber, Southampton; C. C. Lyon, Burnham; E. Seymour, Watford; Hinchcliffe Smith, Halifax; W. J. Southall, Barrow-in-Furness; H. J. Bain, Hither Green; Mrs. G. A. Barton, Birmingham; Thomas L. Winnett, Gravesend; William Stubbs, Blyth Bridge.

Class 15.—First prize (£5), J. Ayton Symington, Kew; second prize (£3), W. Baldwin, Tonbridge; third prize (£2), J. Blount Hopkins, Cardiff; fourth prize (£1), Robert Marshall, Grangemouth. Half-guinea prizes.—A. W. Sargent, Cardiff; Walter Briggs, Hexham-on-Tyne; Oliver G. Pike, Winchmore Hill; J. T. Field, Blackheath, S.E.; J. C. Richards, Bournville; J. O. Samuels, Cheshire; E. Seymour, Watford; Edgar R. Bull, Forest Hill, S.E.; Thomas Sanderson, Clusburn; J. S. Lamb, Campden Hill; Fred Whitaker, Nelson; Sam Swinden, Leeds; A. W. Cooper, Preston; William Harold Wane, Lytham; E. C. Winney, Leytonstone.

Class 16.—First prize (£10), Miss A. M. Walters, Tewkesbury; second prize (£5), W. D. Williams, Hampton Wick; third prize (£3), E. B. Vignoles, Strealey; fourth prize (£1), William Claydon, Plymouth. Half-guinea prizes.—Walter B. Woodland, Leicester; Thomas H. Greenall, Chorley; Alf. Pulford, Scarborough; J. W. Holmes, Barrowford; Charles Kirk, Glasgow; J. Blount Hopkins, Cardiff; Gib. Graham, Girvan; W. A. I. Hensler, South Hackney; R. H. Tomkinson, Liverpool; Mrs. Manson, Bury St. Edmunds; Clarence M. Stead, Chapelallerton; William Rawlings, Hackney; John Smith, Hastings; E. J. Jarvis, Plymouth; Harold Moore, Sidcup.

Class 17.—First prize (£10), H. T. Parsons, Harlesden; second prize (£5), D. Richmond, Paisley; third prize (£3), William A. Clark, Birmingham; fourth prize (£1), W. Northwood, Stourbridge. Half-guinea prizes.—J. Cruwys Richards, Bournville; David Murray, Wolverhampton; Charles Kirk, Glasgow; Henry Robinson, Colne; George H. Halliday, Belfast; A. Stanley Brookes, Clifton; W. G. Hill, Eaglescliffe, R.S.O.; Arthur Black, Nottingham; J. Ayton Symington, London; N. Bradwell, Sunderland; Mrs. G. A. Barton, Birmingham; H. P. Harwood, Rugby; Amy Heimann, Berlin; Brund Wiehr, Berlin; Lewis Lloyd, Birmingham.

Class 18.—First prize (£5), Eric N. Exell, Stretford; second prize (£3), Eric Collinson, Ipswich; third prize (£2), T. H. Collins, Kidderminster. Half-guinea prizes.—B. H. Dawson, Cambridge; E. R. Widdows, Plumstead; J. Peat Millar, Junr., Beith; Master Frank Lovell, Bristol; G. H. Berry, London; James Frank Gunn, Northampton; George Henry Else, Nottingham; Laurence Parkin, Shipley; Harry Foster, New Brighton; Gordon Phillips, Prestwich; Dudley H. H. Temple, Brentwood; Thomas G. Peters, Birkenhead; Thomas Harold Reade, Earl's Court, S.W.; Fred Green, Sunderland; Constance Cook, Warrington.

Class 19.—First prize (£10), W. Renton, Rhodesia; second prize (£5), Gerald Edgar Jones, Auckland, N.Z.; third prize (£3), H. Kinamond, Melbourne. Half-guinea prizes.—H. Amon, Cape Town; E. S. Pegler, Palmerston, N.Z.; Lancelot Ussher, Cape Colony; F. Styant Browne, Launceston; Ed. J. Steer, Cape Town; Robert Lewis Parker, Launceston; Ada Black, Timaru, N.Z.; A. Hardy, Timaru, N.Z.; George H. Mitchell, Melbourne; Matthew Kiernan, Victoria; Claude Phelps, Trinidad; Sam. G. Frith, Auckland, N.Z.; C. J. Ellerbeck, Auckland, N.Z.; R. Hamilton, Singapore; Herbert P. Dickens, Victoria.

PRINTING, etc., for amateurs is now a large department of Messrs. Sanders and Crowhurst's Hove house, which has just issued a neat list of prices. It is sent free from 55, Western Road, Hove.

At the annual meeting of the Photographic Survey and Record of Surrey, which was held on Saturday last, Viscount Middleton highly praised the work done during the year, the number of prints having been doubled, and now totalling close on 1,300, but pointed out that there was still much to be done, and the experiences of similar societies showed that, with increased research, objects were brought to light the existence of which had been unsuspected. As regards the antiquities of the county, no one knew how many more remains of prehistoric man might be found within its limits. The flora and fauna of Surrey seem to have received insufficient attention, and much might be accomplished there by perseverance. Some fine old trees had passed, of which there was no pictorial record. The same held good as regarded churches and other buildings. Surrey had suffered terribly at the hands of the unsympathetic "restorer." Although they were not so rich in architecture as other districts, they could fairly hold their own, and there were scattered over the weald beautiful farmhouses, manors, and cottages well worth preserving. The speculative builder and fire were the chief dangers to which these were exposed, and he was inclined to think that the former was the worse evil.

Photo-Mechanical Notes.

THE EXHIBITION OF PROCESS-ENGRAVING AT SOUTH KENSINGTON.

ALTHOUGH this exhibition has at last opened its doors, one must admit, from even a cursory glance, that the opportunity to see so fine a collection was well worth waiting for. Here we have an exhibition of the growth and extent of the application of photography to illustration, of which those actually engaged in making illustrations are probably not aware, and of which those outside the crafts do not dream.

We have work not only from England and from all over the world, from Sweden and Japan, from the United States and India, no less than sixteen separate countries being represented, besides a historic section which shows the growth of process from the earliest examples, including a proof from the celebrated engraving by Niépce, "The Cardinal d'Amboise," referred to in the historical notes in the BRITISH JOURNAL last week.

The exhibition consists of every kind of process reproduction, exclusive of the commonest of all, viz., monochrome half-tone. There is photogravure by every known variety of method—collotype, two-, three-, and four-colour half-tone, photolithography, in monochrome and in colours from stone and from the metals zinc and aluminium, collotype and half-tone in combination with lithography, gigantography—in short, almost every conceivable process, and most of it in colour. It is, therefore, possible not only to compare the standing of this country with other countries, but to see from the historical section how far possibility is ahead of what it was a few years ago. We must leave a more detailed description of some of the exhibits until next week, meantime advising our readers on no account to miss going to see the collection which is in the Indian Section of the Victoria and Albert Museum, and, when there, not to omit to buy a catalogue, because the introduction is written by Major-General Waterhouse, and contains the most succinct account of the history and details of process-engraving that it has ever been our pleasure to read.

Dry Enamel.

Photo-engravers in this country should have reason to peruse with interest an article in our contemporary, "The Illustrator," in which is advanced a formula for the dry enamel process as one that has been exploited throughout Europe. "There is no question of the genuineness of the formula," says the writer, who gives it as follows:—

No. 1.	
Water	8 ounces.
White rock candy	1 ounce.

No. 2.	
Water	4 ounces.
Citrate of iron and ammonia	50 grains.

Dissolve this and then add:

Chromic acid	35 grains.
Liquor ammonia	$\frac{1}{2}$ ounce.

No. 3.	
Water	4 ounces.
Bichromate of ammonia	$\frac{1}{2}$ ounce.
Albumen	4 ounces.

Great care must be used in compounding this solution, and the formula must be followed in the order given. First grind the rock candy in a mortar and then dissolve it in the water, after which prepare No. 2, adding the liquid ammonia to prevent possible coagulation of the albumen when final mixture is made.

Beat up the albumen for No. 3, dissolve the bichromate in the water and add it, and then add No. 1 to No. 3, and then No. 2 to both very

slowly and with constant stirring. Filter and the solution is ready for use.

The copper plate is coated as in the glue enamel process, and the printing by electric light will require from three to eight minutes, and by sunlight from two to four minutes. This time is for line work. Half-tone negatives require a little longer time.

Development must take place in a special room where moisture can be controlled. Generally this room must be dry, but in the hot season it may require a little moisture. Experience will teach a printer just how much is necessary. The developer is common washing soda (carbonate of soda), which must be ground to a fine powder and dried in the sun until it is pure white. Rub this soda with a tuft of cotton lightly over the print, being careful not to breathe on the surface. Experience, again, must tell you how far to carry the development, but when right it will have a yellowish appearance and be ready to "burn in," which should continue until the print is a light brown. Then plunge the print into a tub of clean water, where it will clear up and be ready to etch. If it does not come off all over it may be cleaned up with a little salt and a bit of cotton.

We have reason to think that the formula given above as having been offered to photo-engravers round Europe is badly "twisted." If the iron citrate and chromic acid were omitted it would be nearer the mark. There is, indeed, no particular secret in such sensitising prescriptions, and one is pretty nearly as good as another. But the instructions given for making the developing powder—baking crystallised carbonate of soda in the sun—are certainly not those which would be offered as a means for obtaining a powder of definite composition. If the dry or anhydrous carbonate is desired as a developer—and we believe it is an excellent one—it can be bought ready for use. If it is to be made, drying the crystallised salt in the sun is not enough. It must be heated to a little short of redness. The most suitable raw material for the preparation of anhydrous carbonate is sodium bicarbonate, which easily loses water and carbon dioxide, on being heated in a porcelain dish, and leaves behind pure dry sodium carbonate.

A French Manual of Photo-Engraving.

In "La Photogravure Pour Tous," by G. Braux (Ganthier Villars, Paris, 1 fr. 50.), the author very tersely describes the making of a screen negative on wet collodion—he ignores dry plates—and the printing of the same by the bitumen and enamel processes. There is also a chapter on photo-zinco in line. The instruction is somewhat meagre, but better than we anticipated after reading in the publisher's circular that photo-engraving was plain sailing to the wet collodion worker, and that the only obstacle in his course was the proper adjustment of the screen at the right distance from the plate.

Dry Plates v. Wet Plates.

In the current number of the "Zeitschrift für Reproductions-technik," Dr. Aarland points out that photo-mechanical gelatine plates have been in use a long time in England and America, but the German process worker has adhered to the use of wet collodion. Experimenting with some gelatine plates which have lately been put on the German market, the author finds them very suitable, and giving results quite equal to collodion, and without the necessity of intensification. The particular formulae recommended by Dr. Aarland are as follows:—

Pyro Developer.

1. Pyro	20 g.
Potassium metabisulphite	10 g.
Water	1,000 ccs.
2. Sodium carbonate	100 g.
Sodium sulphite	150 g.
Potassium bromide	2 g.
Water	1,000 ccs.

For use, mix in equal parts. After fixation the negatives should be washed for a short time, and then immersed for a minute in the well-known citric acid, alum, and ferrous sulphate clearing bath.

Hydroquinone Developer.

1. Hydroquinone	9 g.
Potassium metabisulphite	9 g.
Potassium bromide	2 g.
Water	1,000 ccs.
2. Caustic Potash	18 g.
Water	1,000 ccs.

For use, mix in equal parts.

Removing Ink from Plates.

Among the methods of removing varnish or ink from plates, the following is recommended by Mr. Joseph R. Ford, of the Photo and Process Department of the American Bank Note Co., New York, in a letter to "Process Work":—"I will say that I have also experienced the same difficulty in that line, and, having tried a great many things, I cheerfully offer you my method. Take a piece of blotting paper a little larger than the plate, lay it on a flat surface and pour on a little chloroform. Then lay the plate face down for a few minutes, when the chloroform will frill up the surface of the ink, so that it is then easy to move with turps or methylated spirit."

Exhibitions.

BRENTFORD.

THE seventh annual exhibition of the Brentford Photographic Society was opened on Tuesday last by the Rev. T. Eland, M.A., F.R.G.S., in the Lecture Hall, Brentford Public Library. This is the first year that this flourishing Middlesex society has been able to secure the room, and although not quite so large as the Baths, in which the exhibitions have been heretofore held, an admirably lit and very compact exhibition is possible in the new quarters. The pictures are displayed on tastefully arranged screens around the room, and the show of pictures contains some work of a high order.

A great proportion of the works on view have been forwarded direct from the South London exhibition, and at the conclusion of the present show will be sent on to the Cripplelegate exhibition. The awards of the judges, Messrs. J. C. S. Mummery, Reginald Craigie, and Thomas Bedding, appear to give complete satisfaction, and it is interesting to note that although the exhibition contains most of the pictures winning awards at the South London exhibition, not one of these productions receive so much as a "commended" from the Brentford judges. In the Open Classes a new class has been introduced—"Any Subject; pictures not previously exhibited"—and a surprising amount of first-class work is entered. The silver-gilt plaque goes to H. O. Bannister for "Finishing Touches," depicting a sculptor at work on a life-size statue. This is not only a perfect piece of good technical photography, clean and straightforward, but intelligent use of a knowledge of composition, and what is required to make a picture, is shown. "The Edge of the Common," by Bertram C. Wickison, is awarded the silver plaque in this class. This is an upright picture, pleasing in every particular, and much more pleasingly lit than this worker's "Vesper Hour." Some striking portrait work is also shown in this class by Peter A. Terras, while "A Nocturne in Green" and "Hamo Thornecroft," by R. R. Enfield, are admirable efforts in auto-pastel, but obviously inspired by Steichen's "Moonrise" and "Rodin," shown at the last Salon. J. Fielder Haden has some excellent pictures on view, and shows a keen appreciation of mist effects, but without approaching in any

way "fuzzyism." A. and F. Read's work in this class is also outstanding.

The awards in the other classes of the exhibition are as follows:—

Class B: Silver plaque, "The Morning Mist," Albert E. Bowers; bronze plaque, "Shadows," Arthur Marshall; commended, "The Vesper Hour," Bertram C. Wickison, and "October, 8.30 a.m.," H. C. Leat.

Class C—Lantern Slides: Silver plaque, "Flower and Fruit Studies," E. Seymour; silver plaque, "Four Slides, Various," Rev. H. W. Dick; commended, "Bird Studies," William Farren, and "Assorted," H. Wormleighton.

Class D (Members): Silver Plaque, "A Sussex Lane," H. Gordon Stollard; commended, "In Brittany," H. Gordon Stollard.

Class E: Silver plaque, "In Old Madrid," Hilton Grundy; commended, "The Shepherd," Miss M. A. Newlands.

Class G: Bronze plaque, "Silver Birches," William Squire.

Class H—Lantern Slides (Members): Bronze plaque, Miss M. A. Newlands; commended, Hilton Grundy and A. and F. Read.

WOLVERHAMPTON.

THE fourth annual exhibition of the Wolverhampton Photographic Society was opened by the Mayor of Wolverhampton on Thursday last at the Old School of Art Gallery, Darlington Street. The exhibition is a decided advance on previous shows, and speaks well for the energy of the exhibition secretary, Mr. D. Murray, and the general secretary, Mr. A. Eaton Painter. The loan section was well supported by numerous well-known workers, and examples of different photographic printing processes by the president, Mr. James Gale, formed a considerable entry.

The judges, Messrs. A. J. Leeson and A. E. V. Lilley (of the Municipal School of Art) made the following awards:—Class I.—Medals: "Early Spring in a Birchwood," C. J. Reade; "An Old Mill," F. R. Turton; "Tho' days return and you are gone, I still remain alone," D. Murray; Hon. Mention: "Bridgnorth," E. V. Jones; "The Moated Grange," F. R. Turton; "The Last Rays," C. J. Reade. Class II.—Medal: "Arch and Columns," E. V. Jones; Hon. Mention: "Sheep and Shelter," E. V. Jones; "View on the Worf," E. V. Jones.

G.E.R. MECHANICS' INSTITUTE.

THE members of the Photographic Section in connection with the G.E.R. Mechanics' Institute held their twelfth annual exhibition on the 7th and 8th inst. The judges—Messrs. Furley Lewis, F.R.P.S., A. Mackie, and J. Holden—made the following awards:—

OPEN CLASSES.

Class H (Any Subject): Silver medal, "The Vesper Hour," B. C. Wickison; bronze medals, "The Brewer's Tap," W. Selfe, and "Tugging Home," W. Clayden. Class I (Lantern Slides): Silver medal, set by Rev. H. W. Dick; bronze medal, set by G. A. Booth; commended, set by W. L. F. Wastell. Class J (Stereoscopic): Bronze medal, set by H. Wormleighton.

MEMBERS' CLASSES.

Class A (Landscape): Silver medal, "A Winter Sunset," S. S. Jenkinson; bronze medal, "Winter Sunshine," F. L. Warner; commended, "A Norfolk Lane" and "Among the Pines," A. Woolford, and "The Guardian," A. Cracknell. Class B (Architecture, etc.): Silver medal, "In Blythburgh Church," L. C. F. Robson; bronze medal, "The Baptistery," A. Woolford; commended, "In Ely Cathedral," S. S. Jenkinson. Class C (River Scenery, etc.): Silver medal, "Harbouring," P. J. Perry; bronze medal, also special prize for most original print by a member, "Under a Medway Bridge," F. L. Warner; commended, "The Fury of the Waters," H. D. Banks, and "Time and Tide," A. Cracknell. Class D (Engineering and Mechan-

cal Subjects): Silver medal, "Loco. Smithy," C. H. Day; bronze medal, "Dynamo, Mechanics' Institute," F. Bason; commended, "Climbing the Bank," J. W. Steward. Class E (Miscellaneous): Silver medal, "A Butterfly," W. Salter; bronze medal, "Portrait," L. C. F. Robson; commended, "Portrait," F. L. Warner, and "Daffodils," S. S. Jenkinson. Class F (Lantern Slides): Silver medal, set by A. Woolford; bronze medal, set by H. Restiaux; commended, set by J. K. Ayling. Class G (Beginners): Awards withheld.

CAMERA CLUB.

AN exhibition of the works of Mr. Alexander Keighley has been opened at the Camera Club, Charing Cross Road, W.C., and the undoubtedly high position held by this exponent of photographic art should secure a large attendance of visitors. Most of Mr. Keighley's well-known pictures are on view, and some new ones. Many of these have already been seen at the Photographic Salon, but will easily bear a second inspection. The beautiful composition entitled "Peace" may be regarded as one of the masterpieces of the collection, but there are many others equally as striking. The exhibition will remain open for some time, and the general public will be admitted on presentation of visiting card at any time, while Tuesdays and Fridays, from two to five, have been set aside specially for ladies.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents were made between February 27 and March 4:—

PRINTING APPARATUS.—No. 4,150. "Improvements in photographic printing apparatus." Hervey Heman McIntire, 3, Upper Vernon Street, London.

COLOUR PHOTOGRAPHY.—No. 4,290. "Improvements in three-colour photography." Edwin Tranter Butler, 24, Southampton Buildings, Chancery Lane, London.

FLASH LAMPS.—No. 4,326. "Improvement in photographic flash lamps." Marwood Short, 9, Tempest Hey, Liverpool.

DEVELOPING DISH.—No. 4,421. "An improved developing dish to protect sensitive (to light) surfaces during photographic development." Frederick William Pilditch, 217, Albert Road, Aston Manor.

CINEMATOGRAPHS.—No. 4,423. "Improvements relating to cinematographs, cameras, and the like." Harry Hamilton Moon, 18, Southampton Buildings, Chancery Lane, London.

MAGAZINE CAMERAS, ETC.—No. 4,432. "Improvements in cameras, magazines, plate sheaths, and focussing devices." Henry Major, 24, Carholme Road, Forest Hill, Kent.

CAMERAS.—No. 4,515. "Improvements in photographic cameras." The Thornton-Pickard Manufacturing Co., Ltd., and George Arthur Pickard, 6, Bank Street, Manchester.

FINDERS.—No. 4,555. "Improvements in photographic finders." William Henry Tomkinson, 6, Lord Street, Liverpool.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

FOCAL PLANE CAMERA.—No. 25,379, 1904. "The invention is a camera consisting of a focal plane shutter and a roll-holder. The

specification does not admit of useful abridgment." J. S. Wright, Duxbury, Plymouth, Mass., U.S.A.

HAND CAMERA.—No. 27,867, 1904. "Protection is claimed for a special construction of folding camera comprising in its construction a drop front and extension for long and short focus lenses." J. S. Wright, Duxbury, Plymouth, Mass., U.S.A.

PRINTING PAPER.—No. 25,897, 1904. "The chief claim is for a mixture of agar-agar and starch as the vehicle for sensitive silver salts. The mixture is prepared by dissolving in 4 oz. of water, by heat or boiling, about 100 grains of starch, and mixing with this solution, a solution of agar-agar obtained by boiling 18 grains of the agar-agar in 2½ ounces of water. A little sugar, mannite, glycerine or analogous sugar-like substance may be added to the above mixture when a rather soft coating is desired. About 30 grains of the sugar-like substance to the above quantity is a desirable amount. This preparation, in its non-sensitised state may then be used to coat the paper or other material which is subsequently sensitised. The coating mixture for a self-toning paper contains: Starch, 1½ drachms, dissolved in 3½ ozs. of water; sugar, 30 grains; citric acid, 35 grains; ammonium chloride, 8 grains, and Rochelle salt, 30 grains. To this mixture, after cooling, is added 72 grains of silver nitrate dissolved in 1 oz. of water, 80 minims of gold chloride solution (of strength 1 grain per drachm) with 5 drachms of water. Agar-agar, 13 grains, is finally dissolved in 2½ ounces of water, is then stirred, and the paper coated in the usual way. For an ordinary print-out emulsion the above preparation, minus the gold chloride, is employed." J. H. P. Gillard, 2, Beaufort Villas, Sandycroft, Kew Gardens, and H. H. Molyneux, Rathleigh Gate, West End Lane, West Hampstead.

TRANSLUCENT PRINTS.—No. 6,018, 1904. The chief claim is for a paper support, somewhat more transparent than ordinary printing paper, and less transparent than waxed paper. This material is for sensitising on both sides for the production of a photograph, giving a plastic effect as set forth in patent No. 11,219, 1903. Parchment-paper, as it is called in the trade, is coated on both surfaces with a photographic emulsion. The subsequent procedure is similar to that followed in ordinary photographic work. The duplex material is not only suitable for producing positive photographs, but also for producing negatives; the duplex coating giving depth and roundness, resulting from the slight diffusive power of the medium and the separation of the two coatings. The exposure, moreover, is shortened and halation is absolutely eliminated. In practice, a rather thin printing paper is chosen. This paper is passed through a hot solution of gelatine in ten times its weight of water is allowed to dry, and dipped in a mixture of formaline with 20 times its volume of water and once more hung up to dry. It is then rolled, and both sides coated with an ordinary sensitive emulsion." O. Fulton, 493, High Road, Chiswick, and W. M. Gillard, Glen Rosa, St. Margaret's Road, Twickenham.

New Books.

"*Précis de Photographie Générale.*" By Edouard Belin. Part I. 7 fr.

"*Le Procédé à la Gomme Bichromatée.*" By A. Maskell and R. Demachy. 2 fr.

"*La Photogravure pour Tous.*" By G. Draux. 1 fr. 50 c. Paris: Gauthier-Villars.

M. Belin's aim is to offer a full but elementary introduction to practical photography, and this he succeeds in doing within his 240 pages. Perhaps optics takes more space than it should in a scheme which aims to avoid mathematics; but practically every later page is devoted to matters strictly practical. It is noteworthy that a French writer, when dealing with field cameras, should give the place of honour to English types. M. Belin signals out the Thornton-Pickard "Ruby" as the model of a tourist's instrument.

"Demachy on the gum process" practically describes the second of the above volumes, for the re-issue of an English book, which was the joint work of Monsieur Demachy and Mr. Alfred Maskell, now owes almost all, apparently, to the French author. We are not often accused of an excess of sympathy with the aims and achievements of many pictorial workers whose medium is gum-bichromate, but if the study of M. Demachy's instructions—which are everywhere very precise—can put the gummist in the way of turning out work of the technical character of M. Demachy's, or some of his associates', it has our sincerest wishes for an immense edition. M. Demachy would have his reader distinguish between a print by the gum process and a good gum print, and the distinction is one which we would press upon many persons who seem to imagine that they have only to reproduce an indifferent negative in this manner, and lo! at once it is Art. M. Demachy commands our respect for his marvellous technique in gum-bichromate, and we wish that those who must dabble in gum would take the trouble to study his methods.

The third work, from MM. Gauthier-Villars, is briefly noticed under "Photo-Mechanical Notes."

A "PHOTOGRAPHIC Exposure Note-Book" has been issued in handy shape by Messrs. R. and J. Beck, Ltd., 68, Cornhill, London, E.C. It contains a number of useful memoranda for the photographic tourist, particularly on the use of a telephoto lens.

UNDER the title "Patent Abstracts, Photography," Messrs. Rayner and Co., 37, Chancery Lane, London, W.C., have collected in one strongly-bound volume the official abstracts relating to photography from 1889 to the latest publication. Each "void" patent is so marked, and the value of the volume to those purchasing protection for their inventions is therefore considerably increased. The book runs to 600 pages and contains over 2,500 patents. Patentees and disputants of patents should certainly find this a valuable work of reference. Messrs. Rayner issue it at 21s. net, for which sum they undertake to forward also the remaining publications as they are issued for the year 1904.

"PHOTO-MECHANICAL Processes," by W. T. Wilkinson, has appeared in a third and revised edition from the press of Hampton and Co., Cursitor Street, London, E.C. Several chapters have been added on photogravure, which was not dealt with in the previous issues of the book, and, though nothing is said on machine-printed photogravure, a highly important form of the process at the present time, the instructions are in commendable detail. Those portions of the work which deal with the photo-engraving of line and half-tone blocks

A New South African Photographic Society.—A meeting to consider the question of forming a photographic section of the Scientific Association was held recently in the Library Buildings, Bulawayo, South Africa. The prescribed number of ten having signified their intention to become members, the Chairman (Mr. A. J. C. Molyneux) intimated that the sub-section was thereby formed. The membership fee will be one guinea, and each member will be entitled to the full privileges of the Scientific Association. A monthly meeting of the sub-section will probably be held, and members will then have an exhibition of photographs.

are brought up to date, and many operations and pieces of apparatus are illustrated. The author is apt to give very precise instructions as to how certain things shall be done without explaining why one method is better or worse than another; but his teaching throughout is nevertheless practical, and we can recommend his work as a reliable and comprehensive guide to modern "process." The price of "Photo-Mechanical Processes" is 4s.

New Materials.

The Ilford "Zenith" Plate. Made by Ilford, Ltd., Ilford, London, E.

The gelatine dry plate is sometimes spoken of as though there were but one fixed quality of it and that there were little to choose between the various brands upon the market. That is the inference which might be drawn from the comparisons which are sometimes made by writers between the gelatine process and its predecessor—wet collodion. No doubt it is far from the intention of any writer to convey such an erroneous impression. Almost every one must be aware that the progress which has been made in dry-plate manufacture is as great, if not greater, than that which marked one step from wet-collodion to gelatine. Only a few years ago a plate of great rapidity possessed, and deserved, the character of liability to fog and coarseness of grain; but now we can obtain emulsions of extreme speed in which these defects are conspicuous by their absence. We believe we are within the mark in naming the Ilford "Monarch" plate as one of the modern triumphs of the emulsion maker, and that fact lends additional interest and importance to the issue of another plate, the "Zenith," from the Ilford factories. It is a formidable array of qualities that the makers claim for their new product—fine grain, long range of gradation, freedom from fog, and rapid development, with extreme speed along with these qualities. The plate is offered specially for portrait work, in which the particular combination of properties is more than usually desirable. Samples for testing purposes are offered to the profession, and probably many will elect to come, from their own trials in the studio, to a decision as to the justice of these claims. We may, however, set down here certain facts and figures which prove to us that the "Zenith" plate bears an emulsion of distinctive quality. Of several exposures made on a portrait in a rather badly-lighted room, two were purposely underexposed, and, though development was continued for thirty and fifteen minutes respectively, the negatives are bright and unveiled, and not of the "chalky" character which might reasonably be expected. The plate assuredly possesses "cleanness of working" to a notable degree, despite its speed. In specification of its other qualities, we may quote from determinations made for us by Mr. C. E. Kenneth Mees, B.Sc.: "Grain, examined at 100 diameters magnification, very good. Opacity to blue light of wave length, 4,300, .22 (good)."

This opacity, we would remark, refers to the unexposed plate, and is an index to its latitude.

"Inertia (pyro) obtained by Hurter and Driffield's system, and expressed in candle-metre-seconds, referred to the normal pentane candle, .202, equal to an actinograph or H. and D. number of 168."

The greatest possible steepness of gradation which can be obtained is numerically expressed by Mr. Mees by "2.79, a very high figure for a fast plate."

These figures, which should tell their own tale even to those who are not intimate with sensitometry, show the "Zenith" to be an excellent plate, and one which photographers can be congratulated

at obtaining at the "popular" prices of 1s. and 2s. 3d. in the quarter and half-plate sizes.

The "Owl" Toner for Bromide and Gaslight Papers. Made by Elliott and Sons, Ltd., Barnet, Herts.

The desire for warm-coloured prints that is evidenced not only by the photographic exhibitions throughout the country but by the show-cases of prominent professional photographers in every town has been bound to result, sooner or later, in the introduction of a reliable method of producing these tones, other than those offered by the carbon and sepia platinotype processes. This is especially the case when enlargements are considered, and bromide papers appear to be more popular for the purpose than any other method. Numerous toning processes have been advocated from time to time for bromide papers, including uranium, copper, and the hot alum hypo bath. All have had their vogue, but each seems to have had some drawback that rendered their complete adoption by all classes of photographers impossible.

The sulphide method of toning bromides can, however, now be regarded as one of the best that has so far been advocated for the production of brown tones, and Messrs. Elliott's latest production, "The Barnet Brown 'Owl' Toner," appears to meet the demand in every respect, for a toning process for gaslight and bromide prints, that not only gives a pleasing warm sepia colour, as nearly as possible resembling the rich tone of the standard brown "Barnet" carbon tissue, but a process is offered photographers that is astonishingly easy in application, and as likely to be as permanent as the untuned print. No more than this can be asked for in reason, nor is expected, and our experiments with the new toner amply substantiate all that Messrs. Elliott claim for it.

The toner is sold in two bottles—No. 1 and No. 2. No. 1 solution can be used over and over again, and should be returned to the bottle after use. Its function is to bleach the print, which should be immersed (dry or wet) into the solution, full strength, until all trace of blackness has disappeared, and only a faint image remains. This takes about one minute. The print is then rinsed in two changes of water, and is flooded with No. 2 solution, 1 dram to water $2\frac{1}{2}$ oz. In this solution the print rapidly changes to a rich brown colour, quite evenly, and with no appearance of double toning. It should be allowed to remain for about two minutes, and is then washed for a quarter of an hour in running water, and dried. The process is so exceedingly simple, both in the ease of working and the results obtainable, that it should commend itself to all workers.

Our trials with the new toner show that a slight reducing action takes place during the operation of toning, and that fully exposed and developed prints give undoubtedly the best results. Prints that are somewhat hard, and black and white in character, are not helped to any great extent by the change of colour, but, on the other hand, prints that would be regarded as flat and of a bad colour will undergo a vast improvement by treating with the "Owl" toner. The bleaching solution (No. 1) can be employed as a good intensifier for bromide prints that are flat and weak; the print, after bleaching and rinsing, is redeveloped with an ordinary metal hydroquinone, or other developer (not pyro), when the image is greatly strengthened, and becomes of a rich black colour. Many prints that would otherwise be regarded as wasted will thus be made into presentable pictures. The toner is put up in 8 oz. bottles for 1s., and 1 pint bottles for 2s. 6d., and should be in the equipment of every photographer who uses bromide and gaslight papers.

A NEW CATALOGUE, in a most striking cover, has just been issued by the Lumière N.A. Company, 4, Bloomsbury Street, London, W.C.

It lists the firm's plates, films, papers, and developers, and contains a large number of useful formulae.

Messrs. J. H. Smith, Zurich, Switzerland, ask us to notify that the three-colour plates mentioned last week will be ready early in April, when orders will be filled in the sequence of their receipt.

BLACK MOUNTS.—Messrs. H. and W. Green, Rotherham, are now supplying suitable covers or portfolios for their "Ebona" mounts. The covers are dead black art paper, with some embossed decoration, and are effective if somewhat sombre. They are priced at from 2s. 6d. to 5s. 6d. per 100.

New Apparatus, &c.

A New Kodak: The No. 2 Folding Brownie. Made by Kodak, Ltd., Clerkenwell Road, London, E.C.

The Kodak Company is now putting on the market a new Kodak, which is a folding model of the well-known Brownie, and is called the No. 2 Folding Brownie. This little camera is offered at 21s., a price which brings it within the reach of all, and at which it is exceedingly good value. The design and efficiency of the instrument leave nothing to be desired. Concerning the all-important question

The No. 2 Folding Brownie.

of portability, the No. 2 Folding Brownie measures only 7 in. by $3\frac{1}{2}$ in. by 2 in., and weighs but 15 ounces. The shutter gives three varieties of exposure—time, "bulb," and instantaneous, one trigger release serving for all. The lens is a meniscus of good quality, provided with Iris diaphragm stop with three indicated apertures.

The focussing device is a novel feature, and the new camera derives a large measure of its good value from this useful accessory. The camera springs open in the manner usual with Kodaks on pressing the concealed button at the top of the camera, and the base board is firmly fixed in position by the spring struts at the side. The front of the camera is drawn out by the finger and thumb until it is checked and held by the ingenious locking catch on the side of the base board opposite the finder. This locking catch automatically

The Focussing Catch.

fixes the front at one of three positions, representing respectively 8 ft., 20 ft., and 100 ft. between the camera and the object. All one has to do is to set the catch by downward pressure on the lever A, and movement right or left, to the slot representing the distance at which one is working, and pull out the camera to its

limit. The simplicity of this provision cannot fail to commend itself to all users of the instrument.

The No. 2 Folding Brownie gives pictures similar in size to the No. 2 Brownie, viz., $3\frac{1}{4}$ in. by $2\frac{1}{4}$ in., takes the usual No. 2 Brownie spool, and is loaded and unloaded in daylight. The finder is of the reversible type, for upright or horizontal pictures, and two screw sockets are provided to allow of the camera being used on a stand. The new Kodak is made of wood, and the metal fittings are nickel-plated, giving the camera an exceedingly handsome appearance.

The little illustrated manual supplied with the new Kodak so fully describes the operations of loading and manipulating the camera, the mechanism of the shutter and how to expose, the making of flash-light pictures, removing, developing, and finishing the film, and printing the negative, that even the absolute beginner may be sure of the proper course.

The Kodak Company will send a descriptive leaflet of the No. 2 Folding Brownie to any address on receipt of a request.

The Eclipse Printing-frame Holder. Made by W. Horseman, 25, Florence Road, Stroud Green, London, N.

A convenient attachment for printers on gaslight papers. The frame, which is of stout wire, is slipped over the ordinary gas-

burner, and holds the printing-frame fixed at a distance of about six inches from the flame. When not in use, the frame folds flat. The price is 1s. post free.

A Pinhole "Lens." Made by the Watkins Meter Co., Hereford.

Mr. Watkins has put on the market a series of pinholes, each in a separate mount, of a kind that is instantly attached to a lens-hood not larger than 2 in. The pinholes are conveniently marked on a system, evolved jointly by Mr. Watkins and Dr. D'Arcy Power, of San Francisco, according to which the number on the pinhole is

multiplied by the focal extension. The product is used as the *f* number in calculating the exposure in the usual way, save that the result in seconds is taken as minutes. The convenience of this plan, and of the pinholes themselves, which can be carried without fear of damage, recommends the new accessory to those wishing to adopt the stenopaic method in negative-making.

The "Antinous" Release for Studio Shutters. Supplied by Messrs. W. Watson and Sons, 313, High Holborn, London, W.C.

The release of the shutter used in portraiture should, before all others, be adjusted to work to a nicety as regards smoothness, silence, and certainty, and every photographer has probably found to his cost at one time or another that the pneumatic bulb and tube cannot be regarded as infallible. Rubber is a perishable material, and sooner

or later the time arrives, without warning to the operator, when the shutter fails to respond to pressure on the bulb. For this reason we are glad to find that Messrs. Watson have at length adapted their now well-known "Antinous" release to two patterns of studio shutter, the "Guerry" and the "Silent." The "Antinous" release,

The "Antinous" Release, fitted to Watson's "Silent" Studio Shutter.

we may say to those who are not acquainted with it, is a flexible metallic connection resembling blind-cord in appearance, but with its encased working part composed entirely of metal. Although flexible, the connection between the operator's hand and the mechanism of the shutter is in the nature of a direct thrust, and the shutter can thus be opened steadily—even slowly if required—without the jerk which is frequently needed in working the pneumatic bulb. Absence of vibration is the natural result of such a system, and the release is obviously not liable to miss fire if carelessly handled. Messrs. Watson supply the accessory in such form that the photographer who already has a "Guerry" or "Silent" shutter fitted to his camera can himself replace the pneumatic release by the "Antinous." The change is made in a few moments with the aid of

The "Antinous" Release.

a screw-driver. The price of the release complete, with some feet of connection, is—for the "Guerry" shutter 6s. and for the "Silent" 8s. 6d., and the expenditure of this trifling amount will be fully repaid to the photographer in the smoothness and certainty imparted to his operating.

THE R.P.S.—The following committees have been appointed by the Council of the Royal Photographic Society:—Fellowship Admissions Committee—Pictorial Section: Messrs. H. Bennett, J. Hodges, E. T. Holding, Rev. F. C. Lambert, M.A., Furley Lewis, J. C. S. Mummery, W. Thomas, B. Gay Wilkinson, Dr. C. F. Grindrod. Science Section: Messrs. St. Lawrence Carson, B.A., B.Sc., T. R. Dallmeyer, F.R.A.S., Douglas English, B.A., T. E. Freshwater, F.R.M.S., A. Haddon, Chapman Jones, F.I.C., F.C.S., C. H. Oakden, E. Sanger Shepherd, C. Winthrop Somerville. General Purposes Committee: Messrs. A. W. W. Bartlett, L. E. Clift, Douglas English, B.A., T. E. Freshwater, F.R.M.S., A. Haddon, J. C. S. Mummery, C. H. Oakden, H. Snowden Ward, B. Gay Wilkinson; with power to add to their number. Laboratory Committee: Sir W. de W. Abney, K.C.B., St. Lawrence Carson, B.A., B.Sc., The Right Hon. the Earl of Crawford, K.T., F.R.S., T. R. Dallmeyer, F.R.A.S., A. Haddon, G. Lindsay Johnson, M.A., M.D., B.Sc., F.R.C.S., Chapman Jones, F.I.C., F.C.S., C. E. K. Mees, B.Sc., Professor Raphael Meldola, F.R.S., John Sterry, Alexander A. K. Talbot, Professor W. C. Unwin, Sir Henry Trueman Wood, M.A., S. E. Sheppard, B.Sc.

News and Notes.

THE Ilford £750 Cash Prize Competition.—Our readers are reminded that this competition closes on March 31. Particulars will be sent post free on application to Ilford, Ltd., Ilford, London, E.

ON Thursday, the 2nd inst., the Watford Camera Club held its annual social gathering, at which there was a gratifying attendance. The proceedings included a concert and a whist drive. The club must be congratulated on having held a most satisfactory and successful meeting.

MESSRS. A. E. STALEY AND Co., of 19, Thavies Inn, E.C., write us that they will be pleased to welcome all trade visitors to London, at the Photographic Exhibition, Earl's Court, from March 16 to 30, and to submit to them their new models of cameras, lenses, etc., for the coming season.

THE Edinburgh Photographic Society, which recently held a successful Survey Exhibition, have arranged for another similar exhibition on more extended lines, to be held the first week in December next. Mr. James Burns has been appointed hon. secretary, and his past experience in this connection will go a long way to ensure the success of this new exhibition.

A "TABLOID" Competition.—Messrs. Burroughs, Wellcome are offering prizes of £5 5s., £3 3s., and £2 2s. for negatives developed with "Tabloid" pyro-metol developer. Prints are to be submitted in the first instance, and an empty carton of the developer must accompany each entry form. The closing day of the competition is May 15. Messrs. Burroughs, Wellcome will send from Snow Hill Buildings, London, E.C., a circular of the rules and conditions of the competition.

DENNISTOUN Photographic Association.—Blackfriars Hall, Dennistoun, was on Wednesday evening of last week the scene of a preliminary meeting in connection with the formation of a Dennistoun Amateur Photographic Association. The following officers were elected:—Hon. President, Mr. Peter Whyte; president, Mr. Charles Bathgate; treasurer, Mr. George R. Johnston; secretary, Mr. James Watson, Alexandra Parade. The annual subscription was fixed at 7s. 6d., and the officials were empowered to look for suitable rooms.

OBSCURING the Studio Light.—In reference to a recent reply in the "Answers" column, a correspondent points out that a paint for the purpose is put on the market by Walter Carson and Sons, Grove Works, Lombard Street, Battersea, London, S.W. Mr. Staley, of the firm of A. E. Staley and Co., of Thavies Inn, E.C., have also drawn our attention to the Geka Flexoid ground glass screens, which may be employed for the purpose mentioned by our correspondent. These screens, for which Messrs. Staley are the sole agents in England, are of various thicknesses, and have a beautiful matt surface. The thicker varieties are intended for focussing screens, or can be employed for the improvement of weak negatives. They are supplied in any size, and are comparatively cheap.

THE annual general meeting of the Photographic Society of India was held on February 15 at the society's rooms, Chowringhee, under the presidency of Mr. G. P. Symes Scott. The following were elected for the ensuing year:—President: Mr. A. F. Norman. Vice-presidents: Messrs. Oldbury, Burne, and A. Toucher. Committee: Messrs. A. E. Shorter, T. H. Wilson, C. Cummins, G. P. Symes Scott, W. J. Simmons, H. G. Pearson, R. Baker, S. B. Futché, Count D. de Soligostowsky. Hon. Treasurer: A. J. Olive. Hon. Secretary: Mr. T. R. Pratt. The annual report showed the total number of members to be 464, that a most satisfactory year had been passed, and the financial position was sound. Affiliation with the New York Metropolitan Camera Club has been arranged.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held March 14.—Mr. J. C. S. Mummery in the chair. Mr. S. D. Chalmers, Head of the Department of Technical Optics, Northampton Institute, read a paper on "Some Results in Lens Testing," in which he described the method of testing for lateral aberrations, due in the first place to Professor Hoffmann, and consisting of the separate tracing of the paths of rays coming through the various zones of the lens. A plate, perforated with two or more diametric lines of holes, is placed in contact with the diaphragm, and the behaviour of the lens thus traced in positions in front of and behind the focus. The method which has been modified by the author for photographic lenses is a photographic one, a series of exposures corresponding to different angles being made on one plate. It possesses the advantage of showing, by one operation, both the effect of the aberrations and the portions of the lens coming into play. A second method strongly recommended by Mr. Chalmers as one from which the amateur could himself gain much information as to the performance of a lens, consisted in photographing a flat chart of lines on a plate inclined at an angle of about 15 deg. to the axis of the lens. On the negatives made in this way the curves of coma and astigmatism might be very easily traced. In response to the vote of thanks, Mr. Chalmers stated that critical examination of photographic lenses was undertaken by his department of the Northampton Institute.

DONCASTER CAMERA CLUB.

THE annual exhibition of this club took place in the Dolphin Chambers last week, when about 200 exhibits were submitted to Mr. Godfrey Bingley (Bradford), president of the Yorkshire Photographic Society, and Dr. W. Fisher Ward (Bawtry), and satisfactorily pronounced upon, improvement being the keynote of the judges' award. Ten silver and bronze medals were awarded in five classes, and the following were the winners:—Landscape and seascape: Mr. H. G. Snow, silver; Mr. F. A. Jordan, bronze. Architecture: Mr. H. W. C. Drury, silver; Mr. E. E. Burgess, bronze. Figure studies: Mr. J. W. R. Napier, silver; Mr. F. A. Jordan, bronze. Flowers and still life: Mr. F. A. Jordan, silver; Mr. Drury, bronze. Slides: Mr. W. Gundrv. silver; Mr. Snow, bronze. Mr. C. R. Girdlestone (president) and Mr. T. H. Connor (secretary), with Mr. Snow assisting, supervised the arrangements.

DEVONPORT CAMERA CLUB.—Last year's exhibitions of the Royal Photographic Society and the Photographic Salon were illustrated by upwards of a hundred lantern slides before the members of this club last week. The pictures were introduced by Mr. H. S. Hill, whose efforts in bringing together the collection is to be commended.

BELFAST Y.M.C.A. CAMERA CLUB.—The monthly meeting of this club was held on Tuesday evening of last week at Wellington Place. A new departure was adopted at this meeting. Instead of the customary demonstration, the night was devoted to the useful discussion of photographic questions, such as: What is the use of the swing front and 'swing-back'? What is the most suitable brand of plates for high-speed work, with focal-plane shutter? What developer should be used for snap-shot work? etc. A highly successful and instructive evening resulted.

THE LEEDS PHOTOGRAPHIC SOCIETY.—On Tuesday evening of last week, in the Law Institute, Mr. Alex. Keighley gave a lecture entitled "The Flowers of the Months." Mr. Keighley, in opening, stated that the love of flowers was one which did not die with childhood, but was a love which went with us through life. To the photographer, the study of this interesting branch of the art opened up endless possibilities for pictorial photography. Referring to his methods, he said that the photography of flowers in their natural situations presented some little difficulty, which patience and perseverance would overcome. The camera should be fixed near the ground, and, as wild flowers are mostly small, as near as convenient, considering at the same time the surroundings and the position of view if a pictorial rendering was to be produced. Then, again, focussing sharply on the foreground, a very small stop, and a fairly long exposure were necessary in order that some degree of sharpness might be obtained in the background. There should be no wind, as this rendered the photography of flowers impossible. Other difficulties would be met and overcome with practice. Mr. Keighley showed appropriate lantern slides to illustrate his subject.

CROYDON CAMERA CLUB.—The fixture arranged for March 8 having fallen through, Mr. H. P. C. Harpur gave a short address on the "Art" side of photography, into which was woven "local reduction" by Howard Farmer's reducer. The ethics of "faking" were also introduced. The lecturer was of the definite opinion that an art photographer could be, so to speak, constructed out of an ordinary mortal, in fact, the latter "could be made to grow artistically, like a well-watered bulb in a garden" (a simile which, in some aspects, does not seem altogether kind), but there were several points to be observed in the process. In the first place, the art of "seeing" must be cultivated, and here long-focus lenses gave much truer perspective, as it enabled a more distant standpoint to be taken, with frequently increased atmospheric effect. The elementary laws of composition must also be obeyed, and interest

concentrated, by local reduction, sunning down, and other devices. In reference to local reduction Mr. Harpur showed a very neat method, where the chances of failure appeared to be minimised, and small opaque spots, or even thin lines, would be successfully dealt with. The negative, or transparency, as the case may be, if dry, is first wetted, and the surplus moisture absorbed with fluffless blotting-paper. A weak solution of Howard Farmer's reducer is then taken and applied with a fine camel-hair brush (not wire-bound) to the part requiring reduction. After allowing a short time for action, the negative is rinsed, and the operation repeated as often as may be necessary. The fact that each application of the reducer never occupies exactly the same position as the preceding one obviates any tendency to a hard line showing.

WOODFORD PHOTOGRAPHIC SOCIETY.—The last but one of the series of "Instruction Meetings" which this society is giving for the benefit of beginners, was held on Wednesday last at the Wilfrid Lawson Hotel. Mr. W. L. F. Wastell was instructor on this occasion, and took for his subject "Exposure and Development." The method the lecturer advocated was the employment of one of the many numerous "meters" now in use for measuring the actinic value of the light, of which he instanced and lucidly explained the working of Messrs. Burroughs and Wellcome's and the "Watkins" meter, and then, having thus ensured the proper exposure or somewhere near it—for modern plates admit of an error as great as eight times without seriously affecting the resulting print—Mr. Wastell followed this up by recommending the "factorial" method of time development. A plate is put in the dish, the time noted, and is then covered with a standard pyro-soda developer, the "factor" for which is, e.g., 6. Now, supposing it takes thirty-five seconds for the first trace of image to appear, multiply this time by the factor and 210 is obtained. The theory is that if the plate (covered up) is developed for this time, i.e., 210 seconds, all will be got out of the said plate that it is capable of giving, without the trouble of constantly taking it out of the dish to judge density, thereby running risk of fogging it, staining one's fingers, misjudging the density, and a host of other errors into which it is easy to fall.

HACKNEY PHOTOGRAPHIC SOCIETY.—The sixteenth annual general meeting of this Society was held on March 7. The secretary's report showed that marked progress had been made both generally and financially. The Society is to be congratulated on the sound position in which it finds itself, and also on the fact that it numbers amongst its members such a collection of first-class workers in the world of photography. The recent exhibition showed a balance of £20 2s. 10d. The election of officers for the ensuing year resulted as follows:—President, H. W. Lane; secretary, Walter Selfe; assist. sec., A. D. Fort; treasurer, A. W. Cook; curator, A. J. Linford; lanternist, H. W. Dunkley; excur. sec., F. C. Stimpson; Council: E. Farmer, F. W. Gosling, J. O. Grant, W. Rawlings, F. E. Roofs, Dr. Roland Smith, J. J. Westcott, L. S. Wilks.

SOUTHAMPTON Camera Club.—On Monday evening, the 13th inst., Mr. A. R. Sargeant, the hon. secretary of the Hove Camera Club, lectured on "With a Camera in Egypt." With great lucidity Mr. Sargeant described the belief of the ancient people in the six-fold character of man, and showed pictures of the more recently discovered statues of the deceased kings, which were buried beside the mummy awaiting the ultimate return of the vital essence, the sixth part of the being. A most cordial vote of thanks was accorded him at the close, on the proposition of the president, Mr. W. B. Hill.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.—A meeting of the general committee was held on Friday, the 10th inst., at 51, Baker Street, W. Present: Messrs. A. C. Banfield, F. A. Bridge, Alfred Ellis, Wm. Grove, S. H. Fry, H. E. Hull, Martin Jacquette, A. Mackie, D. Prodger, E. Scamell, Lang Sims,

T. C. Turner and R. Fellows-Willson. Mr. T. C. Turner, president, in the chair. A considerable portion of the time was occupied in the consideration of communications and other matters which it is inadvisable to report. The question of the institution of a Benevolent Fund was finally considered, and it was decided that in the absence of a general expression of desire on the part of the members that the committee should undertake the task, and failing a promise of sufficient support, it was impracticable to carry out the idea, at any rate at present. The committee dinner was fixed to take place on Friday, March 31, full particulars to be announced in the *BRITISH JOURNAL OF PHOTOGRAPHY*.

Correspondence.

COMPETITIONS FOR CASH.

To the Editors.

Gentlemen,—The development of trade cash competitions for photographs taken on a specified brand of plates or films, or printed on a certain maker's paper appears to have grown considerably during the past few years. Not only do the manufacturers regard such competitions as a sure gauge of the popularity and use of their specialities, but the offering of money prizes is often the inducement for photographers, both amateur (*sic*) and professional, to buy a maker's goods expressly for the purpose of entering such a competition, and encouraged, maybe, by success therein, continue to use the materials, to the benefit of both parties. Such is the scheme in theory. On the other hand, one pauses to consider whether the fortunate individuals whose names appear with conspicuous regularity in the award lists of competitions inaugurated by different manufacturers, really do more than satisfy their consciences by the actual production of the prize pictures on plates or papers made by the particular firm offering, for the time being a tempting bait in the shape of not inconsiderable amounts in hard cash. As I read in these competitions are founded to ascertain not only the extent to which a certain maker's goods are used, but more particularly to find the extent of the regular users. It appears, however that the recurring prize winners, who net a very desirable sum of money yearly from this source, obviously cannot have a "one and only love" to whom they pin their faith, and, therefore, much of the object of the competitions—which undoubtedly do a great amount of good in other directions—is nullified.—Yours truly,

ALICE B.

[Our correspondent, who is evidently in "Wonderland," raises a point that may appeal to the organisers of the very successful competitions for cash announced from time to time. We have no doubt, however, that so long as the various enterprising manufacturers responsible for these competitions are satisfied, there can be no reason for anyone to grumble.—Eds. B.J.P.]

STOLEN GOODS.

To the Editors.

Gentlemen,—May I ask you, through the medium of your journal, to make known that, as the result of a burglary on these premises on the night of the 7th inst., the following camera and lenses were stolen, and to warn the trade against dealing with the same:—Vérascope No. 14,198, 45 by 107 m.m., fitted with a pair of Zeiss

Krauss-Tessar lenses, F5.5, Nos. 45,537-8. Thanking you in anticipation for the insertion of this letter,—I am, dear Sirs, yours faithfully,

Lumiere N.A. Co., Ltd.

T. K. GRANT, London Manager.

4, Bloomsbury Street, New Oxford Street,
March 11, 1905.

OBSCURING GLASS.

To the Editors.

Gentlemen,—The following hint may be of service to those who find themselves, as I did recently, with a broken focussing screen. By the following method I can soon rig up a temporary screen, giving even better illumination and finer grain than the ordinary one. Take an old negative according to size of camera, clean thoroughly, and with a weak solution of clear gum or glue smear glass, and apply a piece of paraffin wax paper (such as used by plate manufacturers in packing plates) and rub or squeegee out all air bubbles, thus leaving one with a very good substitute for ground glass.

I have done all my glass in this manner on south side of studio, and thereby softened the light at little cost and trouble.—Yours obediently,

W. BRIGGS.

West Hendon, N.W., March 11, 1905.

[The method advocated by our correspondent is, though not new, certainly one which in its second application may be noted. We frequently receive queries asking for a simple method of obscuring the studio light. For a focussing screen the paraffin paper, we fear, will not prove fine enough for any critical focussing.—Eds. B.J.P.]

THE promise made by the Hon. Secretary of the Royal Photographic Society in the January and February numbers of the Society's "Journal," to the effect that in future that publication would appear on the 15th of the month is carried out in fact this month. The "Journal" was actually published on the 15th, and was in the hands of all members of the R.P.S. on that date.

F. W. WOOD, LTD.—Registered March 3, by P. Becher, 26, Bedford Row, W.C. Capital, £2,500, in £1 shares. Objects: To acquire the business of a photographer carried on by F. W. Wood; and to carry on the business of photographers, manufacturers of and dealers in photographic apparatus, appliances, chemicals, materials and accessories, dealers in optical and scientific instruments, etc. No initial public issue. Registered office, 349, Edgware Road, W.

THE Chemists' Exhibition opened in Covent Garden Theatre, Bow Street, London, W.C., on Monday last, March 13, and closes to-night at ten o'clock. One hundred and twenty stalls make up a very interesting and brilliant show, in which the photographic trade is represented by a number of leading firms. The Rotary Photographic Company exhibit their latest novelties, tri-colour pigment films, and Roto P.O.P. Messrs. Houghtons, Ltd., show a great variety of apparatus in a very well designed stall. Messrs. W. Butcher and Sons occupy three stands, and then have to crowd their many specialties. Among other photographic goods are the chemical preparations of J. E. Lockyer; the Schleussner plates, shown by Thos. Christy and Co., Walsgrove developers and toners, shown by Messrs. Sanger and Sons; cameras and other apparatus, for beginners, of Messrs. J. Theobald and Co.; and chemicals by Messrs. Johnson and Sons, Ltd. A number of prints from a competition promoted by the "British and Colonial Druggist" occupied the Grand Saloon, and could not be called a brilliant lot in any sense, though the first place is certainly deserved by a fine piece of landscape by H. W. Lane.

Answers to Correspondents.

- * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.
- * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

Shaw & Son, 62, Preston New Road, Blackburn. Photograph of Billinge End; Station Road; Market House; and Town Hall. Photograph of Church Street; the Almshouses; Nurses' Home; and Fever Hospital; all at Blackburn.
R. Thirwell, 21, Bridge Street, Stockton-on-Tees. Nine Photographs of S. Coleridge-Taylor.
J. M. Smith, 13, High Ousegate, York. Photograph, Alderney Cove, Suckling Pig. Kate Osborne, 17, Dampier Street, Bridgwater, Somerset. Photograph of a Picture Postcard in the form of a Puzzle.
O. W. Seville, 104, Narborough Road, Leicester. Photograph of the Rev. John McNeill.
G. C. Smith, 3, Seyton Avenue, Langside, Glasgow. Two Photographs of the Rev. Dr. Fergus Ferguson.

G. H., JUSTICE, STUDIO, AND OTHERS.—In our next.

W. H. TAYLOR.—We have handed your letter and enclosure to Mr. Snowden Ward.

TRANSFER OF COPYRIGHT.—The copyrights should be registered by the author of the negatives, who can assign them to you in writing at the time of purchase.

C. N. A.—As the prints were not returned you are entitled to be paid for them. You can sue for the money in the county court, if you think that is worth your while.

J. J. BRISCO.—We think the formula directed treating with chloride of gold solution after bleaching, but we have not found that any of these methods are of the slightest use. The best plan is to make a copy of the print.

A READER.—"Photographische Chronik," published twice weekly by W. Knapp, Halle a. S., Germany. You must get terms from them. A widely read professional organ is the "Deutsche Photographen Zeitung," published by K. Schwier, Weimar.

T. CLEGG (Rawtenstall).—The printer has good points and might possibly be taken up by one of the large houses. But there are several makes of apparatus for a similar purpose already on the market. Better write one or two leading firms and get their views of it. It will be time enough then to take out provisional protection.

CHARACTER DELINEATION.—A seaside photographer delineates character, etc., from the hands free of charge, with a view to attract people to his studio. Could you kindly inform me if he is committing an offence against the law?—OCCULT.

There is no law which will prevent a man from giving anything away, whether it be information or a pound of tea—and certainly in this case there is no breach of the law.

T. W. SMALLEY.—The cost of provisional specification is 20s. and three guineas for one complete specification. These are the actual government fees, but it would be as well for you to find out whether anything of the sort has been done before, or whether you are merely attempting to patent a well-known fact. If you like to write us a description of your process, we will treat it in strict confidence, and tell you all we can on the subject.

SALARY.—We scarcely see how we can advise you in the matter, it seems so complicated by the fresh arrangements that were from time to time made—some verbally and some in writing. It seems that you have already given a receipt, though under protest, for the sum first agreed upon. We should say your best plan will be to consult a solicitor if the sum in dispute is sufficient to warrant your doing so. He will, with all the facts before him, advise you better in the matter than we possibly can.

LEASE OF PREMISES.—(1) I am about taking house for photo business for three years on agreement. Will it be necessary to have it stamped, what would it cost, and where shall I get it? (2) What is the best lens for 12 by 10 for taking groups in small places, outdoor?—**AGREEMENT.**

(1) The house, if taken for more than one year, requires a lease stamp, which may be obtained at any stamp office. The cost depends upon the rent. (2) An R.R. or anastigmat of about 12 in. focus.

PERMITS.—Where should I apply for permission to take photos of public places, parks, etc., in London?—G. G.

For the Royal Parks, H.M. Office of Works, Westminster. For the London parks and spaces, the London County Council, Regent Street, London, W. You will find a list of authorities to whom application must be made for other places in "Photography on Tour" (Dawbarn and Ward, Ltd., 1s.). The "Photographic Red Book" (issued to all members of the Royal Photographic Society and affiliated societies) constitutes a permit to take photographs in most of the public parks and other places of interest in London, a list of which is printed in the book.

FRAMING, ETC.—(1) I am framing some portraits, to hang in our town hall. They are to be oak, stained green. Can you tell me if fuming them with ammonia after staining will make them permanent, as my experience with the green stain has been that they go patchy after a little while? (2) I want some gilt tablets, with names, etc., written on them, similar to those you see in our public buildings, to fasten on them. Where can I get this done?—**FIFTY YEARS A READER.**

(1) Nearly all the green stains used for frames are aniline dyes, and fuming with ammonia is not likely to be of the slightest benefit. Perhaps you are using water stain, which is more liable to become patchy in time than a spirit stain. But no green stain is perfectly satisfactory in this respect. (2) The best person to write names, etc., is a local sign writer.

STUDIO AND LENS QUERIES.—(1) My front room upstairs is 17ft. by 15ft., window facing north, which is 4½ ft. wide and 6½ ft. deep, height of room 9½ ft. Do you think this would do for ordinary portraits, say three-quarter figure, providing I fit up as per sketch enclosed, about seven lights of about 100 candle power, in two rows? These are, in addition to light obtainable from window, or do you think less candle power would answer, providing I use quick-acting cabinet lens and special rapid plates? (2) At about what height from floor do you suggest for lights to be fixed, also size of reflector required? (3) Would it be advisable to have a few lights on other side where there is no window, or would a large glass mirror act as a sufficient reflector? (4) I am fully aware that the length of room is very short for standing figure, but it is chiefly for three-quarter and bust figure that I want; but, perchance, I should be required to take a full figure. What focus of lens would be required for cabinet?—**ANXIOUS.**

(1) We presume that you mean seven lights of a hundred candle power each. A light at 700 candle power is small for portraiture, for you must keep in mind that very little light from the window will reach the sitter, where the sketch shows he is to be placed. If you have less light the exposures must necessarily be long. We should say that when you have busts or three-quarter lengths to take, your best plan will be to put the sitter at the opposite end of the room and use the light from the window only. (2) About 5ft. 6ins., or 6ft. if the lights are arranged as shown. (3) Not necessary if a white paper reflector be used, as the light from the window will, to an extent, soften the shadows. (4) A lens about 9in. or 9½in. will be required.

PORTRAIT IN ROOM.—We have some photographs to do for a gentleman, who requires us to do them at his own place. The room we must operate in has a window facing north, 6 ft. by 6 ft. The window is straight up and down, no slant. Will you give us a hint as to how to diffuse the light? What part of the 6 ft. of light should be blocked out? What distance from the light should the sitter be placed for softest result? We require to turn out a pleasing portrait, nicely lighted, if it can be done. The portraits are head and shoulders, three-quarter length and full-length cabinet size. The room is a large one, 14 ft. by 20 ft.; light paper on walls, window 2 ft. from ground. No space or dead wall betwixt window and background. We have always been used to working at our own place, and will thank you for information.—B. and S.

One would almost have imagined that a firm of professional photographers who know the room would know better how to take the portraits than we should who have not seen it. However, as a rough guide, we should advise you to place the sitter about 6 ft. from the window and facing the centre of the end of the room. Then place the camera as close to the wall, on the window side, as you can. That will give you about a three-quarter face portrait. If the shadows are too strong they can be softened by a reflector, say a sheet or a tablecloth hung on a clothes-horse. You will probably find it necessary to stop off 18 in. or 2 ft. of the window on the background end by drawing the curtain. Anyhow, imitate the light of your studio, which you are used to, as nearly as you can. With such a light at command any professional photographer should be able to produce first-class portraits. For the full-length picture you will require a rather short focus lens.

NOTICE.

Several replies are held over for insertion next week.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

Memorial to Professor Abbe. A proposition is on foot to erect in Jena a memorial to the late Professor Ernst Abbe, whose distinguished achievements in physical science and in practical sociology entitle him to the veneration of all classes in the community. A representative committee, which includes Dr. Czapski, others of the scientific staff of Carl Zeiss, and a number of gentlemen of standing in the optical arts has been formed, and there should be no difficulty in raising money for a worthy memorial. The treasurer of the fund is Dr. Gustav Fischer, Jena, to whom subscriptions may be sent.

The National Physical Laboratory. Last week the annual meeting of the Board of Directors of this institution was held, and numerous visitors were invited to inspect the premises, which are under the directorship of Dr. R. T. Glazebrook. The principal work during the past year seems to have been almost entirely physical, and we presume that the work of organisation and directing has been so great as to preclude any special optical work, which one naturally expects from so distinguished an optical authority as Dr. Glazebrook. Elsewhere we refer to the matter of lens testing, but we also note that the committee hope to establish some primary photometric standard by the radiation from some definite surface at a definite temperature; this is obviously for visual purposes only, but we sadly want some standard photographic light.

Aerial Photography. An international exhibition is in course of arrangement by the Aeronautical Club of France, which seeks to bring together a collection of photographs and apparatus dealing with the aeronautical applications of the camera. The exhibits are to comprise both photographs obtained from balloons or kites and those of meteorological phenomena of which the balloonist makes

a study. The date of the exhibition is not yet announced, but it is asked that prints should reach the secretary, Roger Aubry, 58, Rue Jean-Jacques Rousseau, Paris, before October 30. Those interested in aeronautical photography are further reminded that this work is numbered among the activities of the Aéronautique Club de France, and that Monsieur Aubry, who is known in photographic circles as the editor of that substantial volume the "Annuaire Général de la Photographie," will be glad to come into communication with them.

A Point in Press Photography.

The Institute of Women Journalists assembled last week to hear a discourse from Mrs. Catharine Weed Ward on "The Camera in Illustration," and though mere man was not admitted to the meeting, we have since had opportunities of gathering what Mrs. Ward had to say. One point from what we imagine to have been a witty if strictly practical address we would fix in the minds of photographers who cultivate editors with a view to reproduction fees, and that concerns the various anniversaries and centenaries for which the illustrated Press require photographs. Editors make their plans for these certain events a long time—months, or even years—ahead, and the photographer who submits work a couple of weeks beforehand is doomed to disappointment. He is not merely a week or a month too late—he may be a year or more behind his farsighted competitor.

Photography and Advertising.

We recently commented on the subject of photographers' advertisements, and quoted a certain striking and somewhat humorous advertisement emanating from an American source. Two other specimens which might also be classed in the same delightful genus have come to our notice. An East Anglian photographer advertises in his local paper: "Your own baby, if you have one, can be enlarged, tinted, and framed, like the above, for 6s. 6d."; while in one of the London suburbs this somewhat alarming notice is posted: "Photographic artist. Children executed at any hour of the day or night." Mr. W. J. Casey's series of articles, which commence in this number, on the subject of "Advertising and Photographers," will doubtless appeal to, and should be read carefully, not only by these enterprising gentlemen but by the great bulk of professional photographers who seek publicity in a legitimate way.

Discolouration of Glass by Light.

The paper by Sir William Crookes, which we reprint on another page, deals with a phenomenon which has frequently been noticed in the past in its effect on photographic lenses. That a strong light causes discolouration of the substance of certain glasses is a fact well known to opticians and, from practical experience, to photographers

of the old school. The action, which was observed by Faraday so long ago as 1823, has frequently been found sufficient to make a noticeable difference between two lenses paired for rapidity, when one of them has been employed in strong light for a considerable time. Heavy flint was more liable to change of this kind than the lighter kinds of glass, and peculiarities in this respect have prevented otherwise valuable glasses from being employed in lens construction. Of late years cases of lens discolouration have been little heard of; nevertheless, the counsel of the maker that the instrument shall be exposed to strong light as little as possible is one which the photographer will lose nothing by following.

Sunday Trading.

An ingenious method of avoiding the statute regulating Sunday trading was put forward last week at the Dewsbury Borough Court, when a local photographer was fined 5s. and costs for following his vocation on the Sabbath. He made a somewhat novel request, namely, that he should be fined a nominal sum each week for opening his shop on Sundays, and moreover volunteered the information that when in business at Hull, he opened his shop on Sundays and paid the magistrate's clerk 5s. a week without being called before the court every time. Whether this aspect of the application of the English law appealed to the magistrates as a convenient method of increasing the revenue of the court does not transpire, but it is one that we hardly care to recommend to any of our readers, no matter how enterprising they may be, or an unpleasant surprise in the shape of a substantial fine, founded on a long series of "past convictions," might unexpectedly open their eyes to the error of their ways. As the magistrates stated in the case we quote, the defendant must take his own risk in the matter. We would likewise draw the attention of the ingenious evader of the law to the provisions of the new Sunday Closing (Shops) Act, which has passed its second reading in the House of Lords, and will doubtless soon become law. The object of this Bill is to provide for the closing of shops (with certain exceptions) and the prohibition of street trading on the Sabbath. One of its clauses is that the penalty for an infraction of the law should be 5s. for a first offence, and £1 and £5 for second and subsequent offences. Without wishing to discuss the pros and cons dealing with the necessity for this Act of Parliament, we are inclined to the opinion of the Lord Chancellor, who expressed the belief, during the reading of the Bill, that the importance of Sunday to everybody was being recognised to such a degree that it did not require legislation to stimulate it.

H. and D. Numbers and the "Zenith" Plate.

The necessity of fully specifying conditions in describing sensitive materials is one which a writer cannot keep too prominently before him. The case of the "H. and D." speed numbers is perhaps as familiar as any. The "inertia" of the plate, to which the speed number bears a definite numerical ratio, is intended by Hurter and Driffield to apply to pyro-soda development. But considerably higher readings are obtainable with certain other developers. That fact may be disregarded by some in reading our report last week of the Ilford Company's "Zenith" plate, which, as we pointed out in words, bears an extremely rapid emulsion. Therefore it may be well to emphasise the fact that this speed number cannot be taken as comparable with those of plates which are not speeded for the Hurter and Driffield standard developer. We hasten to refer to the fact, because one case has already come to our notice in which the "Zeniths" had been greatly over-exposed by disregard of the strict sense which we attached to the "H. and D." speed number, and we

would be the more sorry to mislead our readers, inasmuch as some further exposures confirm our opinion that the "Zenith" approaches the extreme rapidity of the "Monarch."

Loan Exhibitions of Pictorial Photography.

The praiseworthy endeavours that occur from time to time on the part of various associations, photographic or otherwise, to bring together representative loan collections of pictorial photographs, are not so frequent as could be desired. Little or no opportunity is therefore afforded the supporters of provincial exhibitions for seeing the work of past masters and other outstanding exponents of pictorial work who have given up exhibiting at competitive shows. This is more to be regretted when it is considered that such work is usually far more worthy of attention than much that is to be found in the average annual photographic exhibitions in this country. A notable effort is, however, now being made by the Fine Arts Committee of the Corporation of Brighton. They have decided to organise a photographic exhibition to be held in the new Corporation Art Galleries from April 17 to June 3. The undertaking will be carried out by the committee in conjunction with the Hove Camera Club, and will consist solely of a loan collection of pictorial photographs lent by those to whom an invitation to exhibit is sent. The exhibition, moreover, will be open free to the public, and efforts will be made to get together a representative show of the best British work, the venture should meet with the success it deserves.

The Proposed Photographers' Benevolent Fund.

It is with some regret, though not without surprise, we see from the report of the last meeting of the General Committee of the Professional Photographers' Association that it was decided to abandon the idea of instituting a benevolent fund in connection with that body. The P.P.A. went to considerable trouble in the matter. It sent circulars to all its many hundred members, asking whether they were in favour of the movement, and whether they would contribute any sum as a start to the affair. But comparatively few replied at all, and of those who did, only a tithe were in favour of it, and the sum promised was quite an insignificant amount. In these circumstances, we think the P.P.A. is wise in not moving further in the matter. Possibly many of those who replied in the negative to the Association's circular, and, perhaps, some of those who did not reply at all, had in mind the result of the old benevolent fund that was instituted some years ago, and the scant support it received from those for whose benefit, in time of sickness or trouble, it was established. Of the desirability of such a fund there can be no question, and certainly there is no body better qualified to carry out a scheme than the Professional Photographers' Association; but if it receives no support it is powerless to move in the matter. "Heaven helps those who help themselves," and the Professional Photographers' Association is judicious in waiting for some change in the apathetic attitude which photographers take towards movements intended to benefit the unfortunate in their ranks.

OFFICIAL TESTS OF LENSES.

Of the many matters in which photographers seek guidance from those who are able to supply it, probably none is more constantly in evidence than the differences in the optical properties of the modern anastigmat lenses. Very frequently the request is couched in such vague terms that it is not possible to give any useful answer. "Which is

the best lens?" is a query as common as it is silly, and about the only reply to it is to tell the querist that he might almost as well ask "Which is the best dog?" But among a class of photographers many degrees removed from such ignorant inquirers as these, are men able to decide for themselves many of the qualities which they desire in a lens to be employed for a specific purpose. It must have such and such an aperture, and such and such a focal length and covering power. But a decision as to these things having whittled down the number of lenses between which their choice lies, there still remains the question of correction of aberrations by which the Gordian knot of value for money must be cut. They would have some authoritative tribunal from which to learn wherein lens A. is better than B., or whether C. equals in performance the maker's claims on its behalf. Two events of last week lead us to draw attention to means of arbitrament which may be unknown to many people. The first was Mr. S. D. Chalmers' paper before the Royal Photographic Society; the second, the annual meeting of the Board of the National Physical Laboratory. Mr. Chalmers stated that the department under his direction at the Northampton Institute, viz., that of technical optics, was open to make tests of photographic lenses. Such tests also are numbered among the activities of the National Physical Laboratory, although only six photographic lenses were examined during the year 1904.

Of course, such facilities are not offered now for the first time. Fourteen years ago the Kew committee of the Royal Society established a scheme under which photographic lenses are subjected to a series of tests for an almost nominal fee, but, unless the demand for the results has greatly increased within the last year or two, the work which was thus done at Kew bore an insignificant proportion to the great volume of trade in photographic lenses. True, the Kew tests were visual throughout, and users of lenses are justified in doubting whether the refinements of a visual test give any correspondingly exact information as to the behaviour of the lens photographically. At the Northampton Institute—so we gather from Mr. Chalmers' paper—the test is a photographic one; the readings are from actual exposures on a photographic plate, and for that reason invite the confidence of the practical photographer. Tests of this character must be of particular value in their application to lenses intended for three-colour work. The method employed by Mr. Chalmers is a modification of that of Professor Hartmann, and is so different from others which have been widely adopted that we may briefly explain the principle on which it rests. The lens is pointed to a small, bright, distant source of light, but instead of focussing upon it, two exposures are made, each equally distant from the true focus. At the point occupied by the iris of the lens system a diaphragm pierced with a series of minute holes is placed, and the results of the two exposures is thus to obtain, for each position of the plate, a series of small circular spots of light, the centres of which may be taken as points on the rays from the centre of the source to the centres of the apertures in the diaphragm. The method can be so carried out in practice that inspection of the negative will show whether the lens is good or bad, and certain defects, such as coma, which are not easy to identify in other ways, are very plainly shown by the Hartmann method. The method can, of course, be carried out ocularly, and we believe that that has been done at the National Physical Laboratory, which, like the Northampton Institute, makes its tests upon the optical bench designed by Mr. Conrad Beck, and described in this journal for January 23, 1903. The apparatus required for the Hartmann method is, however, to be fitted to the bench at the National Physical

Laboratory, and we understand that it is the intention of Dr. Glazebrook, in reorganising the tests, to employ a photographic record of the lens's performance whenever possible.

It is not our present purpose to enter into the extent to which tests should be carried out or the form in which they should be expressed. We have said sufficient to remind our readers that the highest scientific methods are now being applied to verification of the chief instrument in the photographer's equipment.

APPARATUS FOR THE SEASON.

THE season has now arrived when apparatus that has been stored away during the winter months will be required for use again, and the question is, in what condition will it be found? If the precautions we advised towards the end of last season were taken, it will be found in the same state as it was when last employed. But if, as is not infrequently the case, it has been stored in the lumber-room, which, as a rule, is none too dry, things may be very different. Let us take the case of an ordinary field camera, with dark slides, which has been stored in a damp place. It is very probable that the shutters cannot be drawn, or only drawn with difficulty. If any force be applied the glue joints may be strained or the hinges injured, or, if the shutters have been pulled out, they cannot be pushed back; consequently they will be liable to warp or "cast" as they dry, and thus become permanently damaged. The best procedure in these circumstances is to put the slides, as they are, in a warm and dry room and let them rest for a few days—a week or so. During that period the wood will have shrunk to its original dimensions and the softened glue hardened, while the shutters are prevented from warping by the grooves in which they work. What has been said with regard to shutters applies to other wooden portions of the apparatus; if any parts are found to be jammed or work stiffly they should be left to themselves, as, like the slides they will right themselves. In no case should the working parts be eased with glass paper, as is frequently done, as then, when the wood has recovered its normal proportions, they will work too freely, and, in the case of the slides, may admit light. Patience is the best remedy for any trouble that may have arisen from damp storage. The bellows of the camera may have suffered in the same way as the wood-work from damp. If so, it should be expanded very carefully, as, if the gussets have stuck together and they are forcibly pulled apart, some of the outer coating may become removed and light may gain access. The best plan will be to separate them gently, and then allow them to rest with the bellows but slightly extended. If it is opened to its full extent, although it will dry quicker, it will become stiff in the folds, and will not so well shut up again, for it must be borne in mind that the foundation of some bellows is cardboard, and that might cockle to an extent in drying. As regards the metal parts little need be said, as it is scarcely probable that they have suffered by the storage. If, however, any pivots or hinges have become oxidised it will be seen at a glance, and a drop of olive oil, or, better still, one of almond oil, should be put upon them before any attempt is made to work them. As we have just said, patience, and keeping the things in a warm, though not hot, place for a week or so, is the best remedy for months of damp storage; and we might add that the remedy should be applied without delay, as it cannot be completed at an hour or two's notice.

ADVERTISING AND THE PROFESSIONAL PHOTOGRAPHER.

I.

IN dealing with the severe competition now existing in professional photography, the writer of an article in a recent issue of THE BRITISH JOURNAL OF PHOTOGRAPHY stated: "Many a photographer pays for circulars or newspaper advertisements, when he might just as well give the money to a benevolent institution for any good it does him," and inasmuch as he did not go on to show how the money could be more advantageously spent in the direction indicated, one may reasonably infer that his opinion of advertising coincides with that of the majority of professional photographers. Now, is this indifference the result of having thought out the pros and cons of the matter, or is it that the rank and file of the profession are drifting along and paying no heed to the recent development of advertising into one of the most potent factors in modern business life? Believing that the latter is the explanation, we should like to show that there is no reason why advertising should not be more extensively utilised by the profession, and also to briefly indicate a few of the ways in which it may best be used. First, then, perhaps it would be as well to give

A Definition of Advertising.

Probably as good a one as can be found is that given by a leading authority on advertising—viz., "Every move which has for its ultimate aim the sale of anything." At first sight this may appear to embrace too wide a scope, but we hope to show later that it does not. Simultaneously with improved means of communication, cheap books and newspapers, and other causes tending to broaden the ideas and interests of the mass of the people, there has been a rapid increase in the amount of advertising, so that there is now hardly one trade of any importance in which advertising, to a greater or lesser extent, is not used. Little more than half a century ago Carlyle bitterly attacked "The Hatter in the Strand of London," who, "instead of making better felt hats than another, mounts a huge lath-and-plaster Hat, seven-feet high, upon wheels; and sends a man to drive it through the streets," whereas, to-day, he who makes the best goods is, more frequently than not, he who exercises the most ingenuity in advertising them. For instance, does any photographer think that because Messrs. Elliott and Sons charm us with the "Dawson girls," or Messrs. Wellington and Ward amuse us with the doings of "Alphonso and Belinda," that the Barnet and Elstree products are not sufficiently good to sell solely on their merits? And yet has not nearly every photographer as many rivals in his town as have the above-mentioned firms competitors in their lines of manufacture? It may be urged that

Professional Photography is not a Trade.

and that advertising is therefore undignified; but, seeing that banking is also a profession, and one, moreover, in which there is every day more advertising being done, this excuse cannot be taken very seriously. Or another may say that the taking of a negative, submitting proofs, and then obtaining the order for so many copies, is a different matter from selling a tablet of Somebody's much-advertised soap. Granted; but is it a more lengthy process than getting a man to fill up a proposal form, answer some dozens of questions, and then undergo a medical examination—all of which the insurance companies require their customers to do—and yet are not nearly all the insurance companies advertisers? No matter how apparently secure a reputation any concern may enjoy, it cannot nowadays dispense with advertising; younger men enter the

same field, and by their aggressive methods compel the older firms in very self-defence to wield the same weapons, and thus it is that hardly a day passes without our seeing firms, whose names have been for generations "as familiar as household words," joining the ranks of the advertisers. No more striking instance can be adduced than that of the "Times," the venerable "Thunderer," spending thousands of pounds in advertising, first its edition of the "Encyclopædia Britannica," and later its own reduced subscription terms. For better or for worse—it is immaterial to our present purpose to argue which—then, advertising is a force that has come to stay, and no business man can afford to neglect the opportunities it presents.

Having thus briefly outlined the position of advertising in business life to-day, let us consider the question—

Ought the Professional to Advertise?

Turn we to our definition, "Every move which has for its ultimate aim the sale of anything." What has the professional for sale? Is it not the results of his ability to produce photographs—a something which is admittedly not so easily demonstrated as the merits of a tablet of soap, but, on the other hand, is simple compared with the problem which confronts the bank or the insurance company? The object is the same in each case—viz., to persuade the desired customer to enter the doors of the bank, office, or studio, as the case may be, and therefore the bank publishes its half-yearly reports and balance-sheets, the insurance company does likewise, and frequently backs them up with convincing arguments showing how an insurance policy is the best investment for the man of small means, and the photographer does—we will discuss what he does, and what he does not do, later. The first "move," then, is the inducement to come to the studio, and here the comparison with the bank and the insurance company must cease, because the first is practically their only "move," but with the photographer it is but one of a very great number. It is nevertheless a very important one, the most important one, in fact. Let us for the sake of our argument take the case of a country town situated in the midst of a well-farmed district, the dwellers in which are to all intents and purposes resident in the town itself so far as their buying is concerned, and, what is of, to us, equal importance, so far as their reading the two or three weekly newspapers which such a town would possess. In this town there will probably be

Half a Dozen Photographers.

not more than two of whom will have studios in positions that will be passed by the majority of people having business of any nature to transact. If near the railway station they are generally away from the very centre of the town, while if at one end of the main street, perhaps half of the people shopping therein will not pass their studio, so that, be the showcase or window display never so attractive, it will only be seen by a certain proportion of the people. Here, then, is the need for the first "move"—to bring people, desirous in many instances of having their photographs taken, or, if not actually desirous, at least in such a frame of mind that they may easily be persuaded to do so, to the doors of the studio. Can this first "move" be made by any better means than that of advertising in the newspapers already mentioned? In the great majority of cases we think it cannot.

A Signpost.

Occasionally one sees town councils utilising the street lamps as signposts by means of tablets with the inscription, "To the swimming baths." We apprehend that this is done not altogether with a view to guiding would-be swimmers to the baths, but also with the idea of reminding the townspeople that the baths are there in readiness for them—in short, the council is advertising its baths. Now, if Messrs. Hypo and Pyro in the High Street were the only photographers in the town we have instanced, similar signs on the lamp-posts would serve them equally well as advertisements, but if Messrs. Plates and Papers have their studio in the Market Place we see that there is the need for another set of signs, and although they would still serve as such, their value as advertisements would be greatly diminished, and if there were a third studio in another street with its set of directing signs, the value of all three will have become practically nil. It is evident, then, that each studio wants a signpost which shall not only direct the customer to its door, but which shall also offer some particular inducement to pay it a visit. What best fulfils these conditions—a sign which not only directs to Messrs. Hypo and Pyro's studio, but also offers some inducement to go there, and, still further, which can from time to time vary the nature of such inducements? Is there any better means than the newspapers?

The Newspaper Advertisement.

The signpost function of the newspaper advertisement is its most obvious one, and that is probably why the few photographers who advertise in the newspapers have utilised it; but it is remarkable that hardly any seem to get beyond it.

Week in and week out the same advertisement appears with about as much information as that which is afforded by the ordinary visiting card; no particular inducement is offered, nor is any reason advanced why the studio of the advertiser should be visited. One very important possibility in connection with their advertising that is almost entirely ignored by photographers is that of the stimulation of the desire to have photographs taken. How many buyers of the "Encyclopædia Britannica" even knew of its existence, let alone possessed any wish to be the owner of a set of the volumes, prior to the advertising of it by the "Times"? Is not the analogy clear? How is it, then, that photographers so frequently have a photograph ten, twenty, even thirty years old of a recently-deceased person, with the request that they should make a number of copies from it? Nay, even a wretched little scrap of a print from a negative taken with a child's toy camera is brought with the piteous tale, "It's the only one we have; do make the best you can of it." If photography were properly advertised, would this happen once to the twenty times it now does? Again, the majority of the advertisers in local newspapers are shopkeepers who, if they do anything more than give the mere announcement that they have a shop at a certain address, seldom go beyond what is practically an extract from their price list, so that if by the style of the photographer's advertisement, both as to its wording and the form in which it is printed (as the printers say, "its setting"), he can make it distinctive, he thereby gains so much the more value for his outlay.

In my next article I shall submit certain definite suggestions for the drawing up of advertisements which professionals can apply to their own cases.

W. J. CASEY.

THE WEEK IN HISTORY.

How Old is Gum Bichromate?

NEXT Monday, exactly eleven years will have passed since the death of John Pouncy, the man who is usually credited with evolving that wild cat of photographic printing processes—gum bichromate. I was slightly acquainted with Pouncy, some fifteen years before his demise, when he was proprietor of a professional business in the delightful little county town of Dorsetshire, and my recollection is that he was accustomed to disparage his work in gum-pigment printing, and to dwell with pleasure on a method of working up photographs in coloured oils, which he brought to a high degree of perfection. Pouncy received the medal of the Duc de Luynes for his gum process in 1859; but it is curious to recollect that the year of his death, 1894, marked the birth of gum for the purposes of your modern "pictorial photographer." It was in that year that MM. Rouillé-Ladevèze and Puyo exhibited work by the process at the Salon of the Photo-Club de Paris. The "gum" of Pouncy, and gum as it is worked at the present time, though technically the same process, are vastly different in their effects; and probably M. Demachy, who may be regarded as the arch-apostle of the process, would not admit Mdlle. Gomme-bichromatée to be more than eleven years of age.

Be that as it may, it will be well to quote Pouncy's method, which was then called the carbon process, as he originally published it, as then it will be seen (?) wherein it differs from the "gum-bichromate" process of the present day. Three solutions are prepared. 1. A saturated solution of bichromate of potash. 2. A solution of gum arabic about the consistence of thin varnish. 3. Vegetable carbon finely ground in water. Mix four drachms each of 1 and 2 together and add some No. 3. The

paper being laid on a glass plate, "commence coating freely with a broad camel's-hair brush, laying on a copious supply over the whole surface, and then allow the paper to absorb for about two minutes. This done, remove the superfluous liquid thus: Take a painter's 4-in. hog's-hair 'softener,' and work it regularly over the paper, with alternate vertical and horizontal motion, until the whole presents a smooth and even surface, partially dry. The drying may then be completed by the fire."

Cooling Gelatine Emulsion—the Bennett Process.

A simple step, but one which gave immense impetus to the gelatine emulsion process, was that taken by Charles Bennett in 1878. In THE BRITISH JOURNAL OF PHOTOGRAPHY for March 29 of that year, Mr. Bennett first published the working details of a method of making gelatine dry plates of greater rapidity than had before been possible. The innovation consisted in the mixing of the emulsion hot, and in allowing it to stew at this increased temperature. Mr. Bennett's methods would hardly suit present-day emulsion makers, for, after describing the mixing of the ingredients, he directs:—"Shake the emulsion very briskly, and replace it in the kettle for two, four, or seven days, according to rapidity required. The temperature should never be over 90 degrees: if you do not let it exceed that, you will not have red fog. 'Cosy' it up with flannel, and it will not lower many degrees in the night." I, however, use a stove two feet across, and place it on that: a faint gas jet below keeps it always at 90 degrees. I make up every twelve hours. If washed, in two days, the emulsion is rapid and dense; in four days, more rapid and less dense—quick enough for any drop-shutter known."

HISTORICUS.

AN IMPORTANT POINT FOR THREE-COLOUR WORKERS.

In the last number of the "Zeitschrift für Wissenschaftliche Photographie" Herren J. Precht and E. Stenger detail their experiments on this subject, which will be of considerable interest to three-colour workers and also of more general interest to the practical worker.

The distribution of luminosity in the spectrum of daylight has been repeatedly examined visually. We mention the measurements of H. C. Vogel,¹ who compared with a spectrophotometer the luminosity of sun and sky light to a paraffin lamp; further, the work of Crova² on the radiation of diffused sky light; and, finally, the complete researches of Else Köttgen,³ who considered the relative visual luminosities of a large number of sources of light. All these researches agree that the blue rays are considerably in the preponderance in sky light. Köttgen's work differed from the other observers in that he found that the proportion of blue in blue sky light to be greater than in direct sunlight, but this result appears to be influenced by the particular method of the measurement.

Variations in Daylight Actinism.

The actinism of the colours in daylight has not yet been quantitatively estimated; still, H. W. Vogel⁴ made numerous experiments on the variability of photographic action of daylight, by photographing a colour chart, consisting of pieces of coloured paper, under varying conditions. He used the silver eoside plate, first suggested by him, but with this could only estimate actually the blue and yellowish-green action, and was limited to the statement of the order of the colours according to the intensity with which they appeared on the plate. His numerous observations, which were partly made at sea-level and partly on the tops of mountains under manifold meteorological conditions, gave a series of important conclusions on the actinic variability of daylight. Thus he was enabled to state "that without exception the action of the blue of diffused sky light appreciably increased after sunset."⁵

The question of the variability of daylight has become of considerable importance since the discovery of new dyes, and the consequent improvement of the colour sensitiveness of dry plates has given a new impetus to trichromatic photography. In this, one of the most important factors for correct colour reproduction is the correct ratio of exposures behind the three filters, and really this ratio must be kept with much greater accuracy than the correct exposure in ordinary monochrome photography. From this it is obvious that with altered composition of daylight the reproduction of the colours must suffer considerably when the exposures given are according to the filter ratios of normal daylight.

Variations in Exposure-Ratios of Filters.

In order to give some idea of the amount of difference, the following examples may be mentioned. In clear weather and bright equal light on July 20, 1904, the ratio of exposures behind a set of additive filters of Meister, Lucius, and Brüning was estimated at blue: green: orange=1:4:17, whilst with the same ratio on July 22 the blue was so strongly over-exposed and the orange so much under-exposed that the density was photometrically measured, with the result that the ratio of the densities were, blue: green: orange=0.17:0.026:0.032. The result was that to obtain equal densities of 0.17 a ratio of 1:5.8:24.3 should have been given; that is to say, that the green exposure should have been 45 per cent., and the orange 43 per cent.

more. In other words, the green and orange actinism of the daylight had sunk to about two-thirds of the normal.

From such experiments it is clear, on the one hand, that the estimation of filter exposures by daylight must be beset with great inaccuracies; and it follows, on the other hand, that a definite opinion on the amount of the variations that occur may be obtained by exposing at different times. We have made a series of observations on this point, which, however, up to the present, are only few in number, because the time of the year prevents a continuation of the experiments, and, moreover, the experiments have proved that the differences which have been found can only be partly ascribed to the variability of the actinism of daylight.

The Method of Testing.

Our experiments were carried out to approximate as far as possible with practical work. A sheet of white paper was photographed with a three-colour camera with vertical shifting of the filter-holder, the size being 6½ by 18 cm. The distance between apparatus and paper was in all cases approximately 1 metre; the times of exposure were always 3:9:27 seconds, and care was taken, by suitably stopping down the lens, to obtain in a 5 per cent. edinol developer, with 45 seconds development, a medium density corresponding to the half-tones of a normal negative. By a simple arrangement, we were able to make two exposures, with characteristic differences, on the one plate. The difference between our exposures was generally less than might usually occur, as they were all made on the east of the Hanover Technical High School; some in a room so well lighted as to be similar to a studio, others in a verandah in the open air.

The filters are best described by their transmission of the spectrum, and with an arc lamp and a pocket spectroscope, it was found that the following regions were transmitted:—

Blue	λ 410 — 490.
Green	λ 505 — 580.
Orange	λ 570 — 725.

In the following tables we give some excerpts from our experiments:—

TABLE I.

Date.	Time.	Place.	Weather.	Relative Density.		Exposure Ratio.
				Blue : Green : Orange.		
				Measured.	Calculated for Blue = 1	
27/10/04	a.m. 11	In open	{ Sun, clear, bright day }	0.388:0.390:0.392	1.0:0.98:1.01	1:3.2:8.8
27/10/04	a.m. 11.10	In room	In shade	0.359:0.273:0.300	1.0:0.76:0.83	1:5.6:14.0

Conclusions:—All the conditions being kept equal, the exposure in the shade shows a relatively stronger decrease in the actinism of the orange and green than of the blue.

TABLE II.

Date.	Time.	Place.	Weather.	Relative Density.			Exposure Ratio.
				Blue : Green : Orange.			
				Measure.	Calculated for Blue = 1.		
16/11/04	a.m. 11.45	In open	{ Clear, sunny aut'mn day In shade	0.455:0.472:0.473	1.0:1.04:1.04	1:2.7:8.1	
16/11/04	p.m. 3.50	In open		0.718:0.642:0.644	1.0:0.89:0.90	1:4.0:11.7	

Conclusions:—The extraordinary inequality of the exposures in the open produced a considerable deficiency of green and orange action with decreasing actinism.

⁵ Loc. cit., p. 266.

TABLE III.

Date.	Time.	Place.	Weather.	Relative Density.		Exposure Ratio.
				Blue : Green : Orange.		
				Measured.	Calculated for Blue = 1.	
15/11/04	a.m. 10.45	In room	{ Clear, bright	0.864 : 0.828 : 0.863	1.0 : 0.96 : 1.0	1 : 3.3 : 9.0
17/11/04	a.m. 10.30	In room	{ Dull, cloudy	0.263 : 0.210 : 0.177	1.0 : 0.80 : 0.67	1 : 5.1 : 21.3

Conclusions :—Under equal conditions of exposure in clear and very cloudy weather at the same time of day, a strong reduction of the green, and a still stronger reduction of the orange, is shown.

As regards these three tables, it should be noted that the values in each are rigidly comparable, as the two exposures were made on the same plate.

The numbers in the last column show what should have been the ratio of exposures in order to obtain an equal density of 1 behind all three filters, instead of 1 : 3 : 9, which was used. The authors proceed to discuss the ratio between exposure and density, and promise further communications, and state that the general assumption that the density is directly proportional to the time of exposure does not hold good for three-colour work.

Development as a Factor in Colour Records.

Attention is directed to the influence of the duration of development, and, as was pointed out by H. W. Vogel, the yellowish-green sen-

sitiveness is only correctly represented with a sufficiently long development, and this also applies to plates suitable for trichromatic work, though not to the same extent; on the other hand, the colour differences are lessened as the maximum density is approached.

A much more elaborate table is given by the authors, which merely emphasises the differences shown in those already given, and they come to the conclusion that the diminution of the actinism of the green and red rays may amount to as much as 100 per cent., and that any conclusive results can only be obtained by daily experiments.

Seebeck's original statement that in the evening the more refrangible rays are the first to disappear is shown to be erroneous, and this is due merely to the low sensitiveness of the retina to blue and violet, and this has been shown to be so by Helmholtz and König.

Variable Actinism of Arc Light.

In another paper the authors also consider the change in the actinic power of the arc light with increasing watts, using the same screens as mentioned in the first part of the paper, and give a table from which we abstract but three readings :—

Watts.	Blue.	Green.	Orange.
400	1.0	1.01	0.84
700	1.0	0.72	0.68
1,900	1.0	0.68	0.64

The results obtained by the authors open up a wide field of speculation, and are of considerable interest to three-colour workers generally.

THE CAPACITY OF DIFFERENT PRINTING PROCESSES FOR RENDERING GRADATION.*

III.

Characteristics of Carbon.

The general character of the process seems to be that the detail in the higher lights is robust owing to the absence of any abnormal falling off, such as I have described in speaking of P.O.P., while in the shadows contrast is well maintained almost to the last gradation. There is, however, little of the flattening already described, owing no doubt to the light having to penetrate more and more of the opaque tissue the greater the depth of shadow.

To some extent its characteristics must vary with the opacity or covering power of the pigment used, and the quantity of it in the tissue. I have used in my experiments black tissue, but for comparison have also tried sea-green and terra-cotta without finding any important difference in gradation. There is, however, the difference due to colour-contrast, the red print being of course distinctly lighter in tone throughout.

It is generally understood that for carbon printing with a normal 4 or 5 per cent. bath, a "plucky" negative is required, yet it seems that the range of gradation and steepness is much the same as P.O.P. I think the need for a contrasty negative is due to the very vigorous rendering of detail in the lights, necessitating a corresponding vigour in the shadows; that is to say, the negative should employ a large part of the available gradation, otherwise the print may appear flat owing to the comparative strength of the detail.

Non-transfer Processes.

The direct printing pigment processes, gum-bichromate, artigue, and its congeners, do not properly come within the scope of my paper, because I assume that they are seldom, if ever, used by their devotees without some artificial interference with the gradation. I would only remark that the depth of shadow will depend largely on the

amount of pigment used in preparing the coating, and the purity of the lights on the kind of paper used.

I have prepared two kinds of paper, one a glazed writing paper, the other a rather rough open-textured paper, using a fairly opaque coating. The development was unassisted in cold water, and the gradation appears to be very short, only about 1 to 5 or 6. On a part of the paper I have used abrasion, and it will be seen that the smooth paper gives a clearer high-light than the rough. (Since this was written, I have seen a print on a commercial paper of this class in which the lights were quite pure. The character of the print seemed to indicate a very short, steep gradation.)

Platinum Printing.

I have tested the three brands of platinum paper most used in this country. All these are development papers for use with cold solutions. They have a good range of gradation, but one in particular has the longest range of any daylight printing process, and this particular paper should be specially useful when a negative of unusual "pluck" is to be dealt with. With average negatives there is little to choose between the three, although the prints will differ slightly in contrast according to the paper used.

It is usual to say that "you want a plucky negative for platinum printing." The reason lies in the uniform character of the gradation. From the faintest stain up to the fullest black the steps go up at a steady increase. There is no falling away in the lights, no softening down in the shadows, as there is neither discoloured film to act as a screen during exposure, nor degradation in fixing. Hence every tone in the negative is rendered in its true value, and as the deepest shadow is a deep pure black, a very long range of tones is available which a flat or thin negative cannot fully employ. Hot development, although it decreases the exposure necessary, does not increase the number of

* The previous portions of this article appeared March 10 and 17.

gradations rendered. It warms the colour, and I think slightly adds to the "pluck" of the print.

Gradation with Platinum.

It is a peculiarity of platinum papers that when the maximum depth they are capable of rendering has been reached, a sort of reversal sets in, so that the shadows actually grow lighter with prolonged printing; this of course can only happen when the negative has too much contrast for printing by this process. That, however, is almost the same thing as saying it is too dense for anything. The gradations rendered vary from about the same as P.O.P., 1 to 128, to 1 to 400, which is several tints more than any P.O.P.

Choice among Daylight Processes.

In dealing with these daylight processes my aim has been to find their extreme limits. Probably in actual practice these limits are seldom used to their full extent, but I hope I have made it clear that even with negatives which do not call for the full range of tones the paper is capable of giving, there is considerable choice in the character of the print. There is of course no control, except in the case of carbon, and the only way to change the character of the print is to use a different make of paper. How great the control is in this sense may be seen in the examples I have made. All are from the same negative—one having a range of from 1 to 40.

Contact Printing by Artificial Light.

Coming now to processes used with artificial light, such as bromide paper, we meet with new conditions, as the gradations of these papers vary according to the treatment they receive as regards exposure and development. My first experiments were made with a view to finding the range of tints obtainable when development is pushed to its full extent. The range of gradation attributed to bromide papers by even recent writers is as low as 1 to 16, and it was a surprise to me when my first experiment yielded gradation far exceeding that. Fearing that after all my screens were at fault, I tried a new tack, and made graduated exposures direct to the light by means of a dark slide. Leaving a strip unexposed, exposures of 1, 2, 4, 16, 32, 48, and 64 seconds were given to successive strips of the same sheet, and on development the result was as follows: all these gradations are clearly rendered as far as 48 seconds, and even the difference between 48 and 64 is distinguishable, although possibly not to a useful extent. As it is evident from the strength of the 1-second strip that $\frac{1}{2}$ second would have given a useful tint, the paper is capable of printing from a negative having a gradation 1 to at least 96 without loss of detail in either lights or shadows, and with care it would go as far as 1 to 128. This is one of the latest papers placed on the market, and no doubt embodies the latest improvements in manufacture, but there are others which show quite as great a range. On the other hand there are papers giving a much shorter scale, and these are suitable for thinner negatives.

The Different Conditions in Enlarging.

It must be noted that I am dealing only with contact printing. When these papers are used for enlarging, the optical conditions are such that the negative is practically intensified, its half-tones and high lights becoming much more opaque in comparison with the shadows than when it is used in contact with the paper, and the greater the enlargement the greater the intensification. It seems to me that ignorance or neglect of this peculiarity is largely to blame for the gloomy aspect of our exhibitions these last few years since enlarging became the fashion. It is hopeless to expect that a negative of the proper contrast for P.O.P. will yield a good enlargement on bromide paper, for in the attempt to get detail in the lights the shadows will be overdone, and the result will be one of these pro-

ductions seemingly taken "twixt the gloaming and the mirk," which are only too familiar.

Time has not permitted me to experiment with the enlarging value of negatives, but I do not think the gradation should exceed 1 to about 16 (contact value). Such a negative would not be useful for printing-out, but it could be used in contact with gaslight papers, also some bromide papers with proper treatment in exposure and development.

Bromide Papers Contact-Printed.

Returning to contact printing, I may first compare bromide papers in a general way with P.O.P. and the other processes already dealt with. We are accustomed to call bromide prints black and white, but when compared with P.O.P. the black appears but a grey, and as a matter of fact the scale of gradation is not so steep as one would expect. The matt surface which most of these papers possess no doubt produces greyness to some extent, partly by permitting scattering of light, but also by virtue of the starch which I understand is introduced into the emulsion for the purpose of creating a dull surface, and which no doubt dilutes the black of the silver. Further than this, however, it can be seen from the example of glossy bromide that the silver itself is rather grey as compared with P.O.P. or black carbon.

The Range of Gradation-Ranges.

In testing these papers I have used as a normal developer two grains of amidol in each ounce of 5 per cent. sodium sulphite, with two drops of 10 per cent. potass bromide to ensure absence of fog. This developer is sufficiently concentrated to give the deepest black the paper is capable of producing, and the amount of bromide is too small to affect the gradation.

Under these conditions when development is carried to the point at which all further action ceases, the majority of the papers I have tried give seventeen tints, equalling a range of gradation in the negative of 1 to 128; one gives a very short range, fourteen tints, equalling 1 to 48 (that is one of the older brands); another gives fifteen tints, equalling 1 to 64; and another sixteen tints, equalling 1 to 96.

How Contrast Falls Off.

Thus it appears that most of them are quite capable of dealing with negatives of normal contrast, such as are suited for P.O.P. It has to be noted, however, that bromide paper is subject to rapid falling off in contrast towards the ends of the scale even to a greater extent than P.O.P., and it is doubtful if some of the tints at the ends would be distinguishable from each other if scattered about as in a print.

The falling off in contrast is due to a different cause from those described in speaking of P.O.P. It must be remembered that bromide paper, like bromide plates, has periods of under, correct, and over-exposure. In the high lights the conditions are those of under-exposure producing rapid falling off in contrast; in the middle tones, which form the really useful part of the scale, there is the period of correct exposure, characterised by regular increases of opacity; in the shadows the period of over-exposure appears with its characteristic falling off in contrast so that the last few tones are hardly distinguishable. Modification of the developer, leading to incomplete development, alters the scale considerably. A weakened, that is to say a diluted, developer lengthens the scale, provided, of course, development is not continued too long, for ultimately even a dilute developer would give the same reduction as a strong one. By dilute I mean double to three times the quantity of water, and under these circumstances I find the scale lengthened to eighteen tints, equalling a negative of 1 to 160. Great dilution—ten to twelve times the water—leads to a condition which Winthrop

Somerville describes as incomplete reduction of the silver. Possibly the image then consists partly of Carey Lea's photo-bromide. However that may be, the range of gradation is very great, as may be seen in Nos. 8 and 9. The colour, however, is very bad—a sort of whitish-brown. By reducing it to haloid and redeveloping with a strong developer, the colour is improved to grey, but the scale remains very flat.

Alterations in Gradation.

The very remarkable influence of chromic acid or a bichromate on gradation calls for notice. In this country it was first described by Mr. John Sterry, but I believe the discovery is claimed by the Italian Professor Namias. Exposure is given sufficient for the highest light, and by treatment with very dilute chromic acid or bichromate solution previous to development the over-exposure of the shadows is corrected. I have made examples of long exposures behind my screen, one developed normally, the other treated with 1/1,000 chromic acid for two minutes. The first, of course, shows the normal number of tints for the paper, followed by long tracts of uniform black; the second shows gradation throughout, indicating that it could print from a negative of gradation reaching to thousands—far beyond the possible gradation of any ordinary plate. In preparing these examples I have continued the action of the chromic acid too long, thus losing one or two tints in the lights, but with proper adjustment that would not happen.

Excess of bromide in the developer shortens the scale considerably, but as in the case of plates it must be present from the beginning. Example Nos. 7 and 15 show that, even with amidol, two grains per ounce of bromide shortens the scale two or three tints, thus enabling a thinner negative to be used. With a harder working developer, such as hydrokinone, of course the shortening would be greater still, but it must be remembered that there is a limit to the permissible quantity of bromide, as the colour of the image becomes disagreeable when over-restrained. The composition of some developers used for bromide papers rather puzzles me. The idea seems to be to add alkali to make it strong, and then bromide to make it weak. A developer such as amidol, which will work cleanly with little or no bromide, seems more rational, and avoids any shortening of the scale.

Exposure and Gradation.

The time of exposure influences the character of the gradation. Long exposure flattens the print by fully exposing the lights and giving full detail, while it over-exposes the shadows, causing them to decrease in contrast. Short exposure allows full contrast in the shadows, but loses detail in the lights. The distance of the light or strength of the light has also an influence. Powerful illumination reduces the effect of under-exposure in the high lights and increases the over-exposure in the shadows, while weak illumination has the opposite effect. Two samples will describe this better than words. They had equivalent exposures at 2 and 6 feet from the light, and while the number of tints is equal, the difference in character is quite clear.

"Gaslight" Papers.

Lastly come the gaslight papers which have become so popular in recent years. As originally introduced these papers had an extremely short and steep range of gradation requiring thin negatives and necessitating great care in exposure to avoid exaggerated contrast. Such papers are still in the market, and have their uses, but other varieties with a longer scale have been introduced, suitable for negatives of moderate gradation. Amongst the recent introductions I find one which equals in this respect some of the older bromide papers. The difference in character of the various makes of these papers is enor-

mous, and the photographer who does much printing on this medium would do well to have several different brands at his disposal to suit different styles of negative.

Amongst the brands I have tested there are papers giving gradations 1 to 8, 1 to 16, 1 to 25, and one of recent introduction, 1 to 64, which equals a slow bromide. These are the gradations of negatives most suitable for the brands of paper, but that is not to say that negatives of longer scale cannot be printed on them. They can be dealt with by giving full exposure and using a somewhat diluted developer, but as it is necessary to use the whole scale of tones in order to bring out detail in the lights, the print will be too harsh in contrast. Longer exposure which would bring out the detail at an earlier stage would tend to block up the shadows, while greater dilution of the developer, although it would give a softer result, would injure the colour. On the other hand, a negative within the proper capacity of the paper will give a soft or a brilliant print at will according to the duration of development and the amount of exposure while retaining the pure greys and blacks which are characteristic of the process. Thus, in one example, my 1 to 40 negative is printed on a 1 to 8 paper, with the result that the print is undesirably "brilliant." A print showing the result of over-development in giving dense and inky shadows is very easy to achieve by the use of a rapid developer. Bromide cannot be used to slow development, as it spoils the colour, nor can dilution be resorted to unless a warmer tone is desired. Prolonged exposure followed by very dilute and restrained development gives warm colours owing to incomplete reduction of the silver, probably with formation of photo-chloride.

Development with excess of bromide and carbonate of ammonia to obtain red tones shortens the scale, but the colour contrast is small, tending to give a flat print.

The Negative and the Printing Process.

A few words as to the means of suiting negatives to processes must conclude my paper. We have been told by Messrs. Hurter and Driffield that to obtain equal degrees of contrast all plates must be developed for an equal time at an equal temperature, but the temperature is just the difficulty, as few of us have facilities for regulating this factor. Mr. Watkins by his factorial system of development overcomes the temperature difficulty, provided exposure is reasonably correct, but in the case of varying exposures factorial and time development give different results. That, of course, need not matter to users of the factorial method, as its author supplies the means of ensuring correct exposure.

I do not think, however, that these methods of development by rule will ever appeal to the great majority of those who use photography as a pastime. There is an interest and fascination about "working up" a negative during development which will always appeal to most of them, whether they really control the result or not—they will continue to believe that they do.

Correct Exposure v. Development.

Personally I have long ceased to believe in the efficacy of "tentative development," believing that the character of the negative is governed by the exposure given to the plate and the time allowed for development. I do not overlook the effect of restrainers or of dilution, but I contend that the necessity for either must be known before the developer is applied to the plate.

The learner in photography would do well to spend less time in the dark room practising the art of "tinkering the developer," and more time at the fireside studying the factors that govern exposure. Having acquired the art of exposing correctly, he may "tinker" as he likes, and he will probably get a good negative just as he would have done had he developed straight away.

The great point is to so expose that the contrast required by the printing process in view will be secured without having an unduly dense or thin negative.

The Latitude of Modern Rapid Plates.

Uniformity of working conditions will greatly aid in attaining the art of stopping development at the proper stage. There seems to be little need for using different kinds of plate nowadays, as plates of great rapidity have now as much "latitude" as any one need desire. As a matter of fact, amongst the plates I tested for range of gradation, that one which gave the greatest range and therefore the greatest latitude in exposure was also one of the most rapid in the market. Therefore it is better to find a plate that pleases you and use no other. Knowing its characteristics, you will then know when it is "dense" enough. There is no need to try every developer you hear of. That sort of work you may do as an experiment, but when you want negatives use one formula which you have found to suit your plate.

Then as to temperature, although it is admittedly difficult to regulate this factor, extremes can usually be, and should be, avoided, as the influence on results is great.

The dark-room lamp is another factor which should be regular, as

with a varying amount of light judgment of density is apt to be faulty.

Stain as a Disturbing Factor in Negative Making.

Another very important factor is pyro-stain or developer stain of any kind. I do not refer to general stain, affecting the shadows—careful worker will have that to contend with; but I refer to the graduated organic image deposited along with the silver, and in something like the same ratio. This must have a very disturbing influence on the printing value of the negative, as may be seen in examples I have made. They are plates exposed in graduated strips and developed in pyro-soda without sulphite. The silver having been dissolved out, it is possible to obtain quite a respectable print from the pyro-image. The extent to which this stain exists depends entirely on the amount of sulphite present in the developer, and as the sulphite in a stock solution is constantly decreasing by oxidation, the amount of stain will increase with the age of the solution. I am quite aware that many workers consider this stain desirable, but it is hardly under control, and I think that when uniform negatives are aimed at it would be better to depend on silver alone for density, and to use a freshly prepared developer, or one of non-staining character.

WILLIAM GOODWIN.

THE COLOURATION OF GLASS BY NATURAL SOLAR AND OTHER RADIATIONS.

[A Paper read before the Royal Society.]

It is well known that many samples of colourless glass containing manganese slowly assume a violet tint when exposed to sunlight. This effect is frequently seen in plate-glass windows having a southern aspect; watched from year to year they assume a more and more pronounced amethystine hue. The introduction of manganese into glass is to neutralise the colour caused by the presence of iron. Iron gives the glass a greenish tint, and the addition of manganese binoxide performs the double object of oxidising the green protosalt of iron to the persalt, and also of imparting a purple shade which neutralises the green-yellow tint of the silicate of peroxide of iron.

Violet Discolouration of Glass.

In 1903, I received from two separate correspondents specimens of glass coloured an intense purple. I quote the following sentences from the covering letters:—

Mr. A. Ernest Williams writes:—

"While residing at Uyuni in Bolivia last year, at an altitude of nearly 4,000 metres, my attention was called to the fact that all transparent white glass when thrown out on the 'Pampa' in a short time assumes a violet hue, which becomes more marked with time. I was told that all specimens were thus affected, and that when taken to sea level at Antofagasta they lost their colour. This latter statement I hardly believe, as I have had some pieces with me now on low level for nearly a year, and they have not lost the colour.

"I now notice that all transparent white glass thrown on rubbish heaps, even at low level, assumes this violet colour, though only to a slight degree, and I am curious to know the cause, being more interested since reading that radium so affects glass.

"I may mention that Uyuni is situated on the great central plain of Bolivia, which plain has evidently formed the bed of an inland sea or lake, for I have found quantities of minute shells there. Not far off to the S. and S.W. are borax fields, and still further west, nitrate. To the N.E. are the mountains of Pulacayo and Cuzco (not the great Cuzco), and electrical disturbances are of almost daily occurrence. I can fully confirm Sir Martin Conway's description

of the battles between the mountains, where lateral discharges are plainly visible. I am sending you by post a small specimen of the glass."

About the same time I received some specimens of purple coloured glass from Mr. Thomas Wilson, from Iquique, Chile. In a subsequent letter answering some inquiries, he sent a further quantity of the coloured glass, saying:—

"You will notice a great variety in the depth or degree of tint in the different pieces, which may be attributable to the varied length of the exposure of each to the action of the sun's rays. It seems to me that some of the pieces have lost somewhat of their depth of colour since I picked them up, but this may be an impression only. The two pieces forming together the bottom of a broken tumbler, and which have a deeper tint than any of the rest, were found about twenty paces apart in an old Oficina that had been uninhabited for twenty-seven years. It is impossible to give any idea of the length of exposure of the remaining pieces to the sun's rays, as I have obtained them from all parts of the Pampa over an extent of nearly 100 miles. The samples I send you were originally white glass, and although an abundance of glass of various colours are to be found, yet I send you none, as it would not be easy to say what their original colours had been previous to exposure."

The Action of Light of Short Wave-Length.

The pieces of glass referred to above are of all depths of tint, from deep violet, almost black in thick pieces, to pale amethyst. Analysis shows the glass to contain manganese. Heating the glass in a covered crucible to its softening point, discharges the colour, leaving the glass white and transparent.

The colouration is not superficial. On immersing a piece of a coloured glass in a liquid of about the same refractive index as itself, the colour is seen to have penetrated throughout the mass.

At first sight the explanation of this phenomenon would seem to be that it is produced by the action of light, the intense radiation occasioning a re-arrangement of the oxygen molecules in the glass,

the ferric salt becoming ferrous, and the manganous salt changing to a manganic compound.* The change of colour might then be expected to be noticed in any part of the world where broken glass is thrown about and the sun's rays are very intense. In the Transvaal, where both these conditions are well fulfilled, I have neither heard of nor noticed any such colouration, and it would be interesting to hear if travellers in other tropical countries have observed any such change of colour of glass.

Probably height above sea level has much to do with the phenomenon. At a height of 4,000 metres nearly half the atmosphere is beneath one's feet, and that which remains will allow rays of shorter wave-length to pass through than the atmosphere at sea level will transmit.

An Alternative Explanation.

For this reason it is not necessary to invoke another mode of explanation that might possibly suggest itself. It now has been well established that many natural bodies, water from great depths, some samples of earth and rock, air from underground sources, together with some minerals, are more or less radio-active. Radium, acting for a few days, even though quartz, will produce as intense a colouration in a piece of this glass as exposure to the sun on the Pampas has taken years to effect. It is hardly conceivable that there can be a special radio-activity of the soil in certain parts of Chile and Bolivia sufficiently powerful to produce the effect.

A piece of the coloured glass, bleached by heat, was put close to a quartz tube in which about 15 m.grams. of pure radium bromide was sealed up. In the course of a few hours a faint amethystine tint could be distinguished on the glass, and in a week the tint was equal to the deep colour of the unbleached specimen. A duplicate piece of the same glass which had been bleached by heat, kept away from radium, has remained colourless for seven weeks.

A piece of the deepest purple coloured glass was put on a sensitive photographic film, and kept in the dark in contact with it for thirty-four days. No trace of action could be detected on developing.

The purple glass which had been bleached by heat and then coloured purple again by radium, was put in close contact with a sensitive film for twenty-four hours. On developing, no trace of action could be seen.

Darkening by Radium.

The darkening effect produced by radium on bodies exposed to its emanations is very general. Quartz, mica, glass of all kinds, and the

diamond may be specially mentioned. In a paper recently read before the Royal Society "On the Action of Radium Emanations on Diamond" (Roy. Soc. Proc., June, 1904, vol. lxxiv., p. 47; and "Chemical News," 1904, vol. xc., p. 1), I showed that the β -rays (electrons, and γ -rays not only effected a superficial darkening, converting the surface of the diamond into graphite, but the body colour of the stone was changed from pale yellowish brown to bluish-green; and I suggested the explanation that the action might be chemical, the ferric state of the iron being reduced to the ferrous state, and the colour thereby changing from yellow to blue-green.

Photographic Experiments.

In the year 1855, I tried a series of experiments with a spectrum camera furnished with two quartz prisms and a quartz lens, with the object of ascertaining if the atmosphere exerted any absorptive action on the more refrangible rays of light. Photographs of the solar spectrum were found to reveal lines of higher and higher refrangibility the nearer they were taken to midday; and, arguing from this, I concluded that the "noon-day spectrum at midsummer ought to contain more and higher rays than are possessed by the corresponding spectra at any other time of the year." The examination of the photographed spectra was continued through the summer, photographs being taken at noon whenever the sun was clear, and I found that "as the light came less obliquely through the atmosphere, new rays began to be apparent; until at midsummer, when the sun was on the meridian, I succeeded in obtaining evidence of the existence of rays which the most prolonged exposure failed to detect at any other time."

I may perhaps be pardoned for quoting from my paper on the subject the following passage, written fifty years ago ("Journal of the Photographic Society of London," vol. ii., p. 293):—

"Some curious speculations arise from these facts. Should we be able, by working under a vertical sun, and with every advantage of cloudless sky, etc., to increase still more the length of our spectrum? Can we attain the limit of solar refrangible rays in this direction? Or is it not more likely that there are emanating from the sun torrents of rays which never approach the earth—rays which, beating against the upper stratum of the atmosphere, are themselves destroyed, but whose vibrative energy is transmitted to us with increased wave-length and lowered refrangibility, in the form of heat or light?"

Sunlight and radium both produce similar effects in these respects. Their modes of action are known to be in the main very different; but it has been clearly shown that, in general, variation of time being disregarded, what radium is capable of doing in the way of inducing chemical change, ionising gases, producing phosphorescence, and impressing a photographic plate, sunlight will also effect.

WILLIAM CROOKES, D.Sc., F.R.S.

* In this connection it may be of interest to recall the fact that in the early days of photographic research the ultra-violet rays of the spectrum were called the "oxidising rays."

A LECTURE on Plant Photography.—In a lecture by Mrs. Dukin-Beld H. Scott at the Athenæum, Richmond, on Monday evening last, on "The Movements of Plants," the many fascinating subjects in the plant world possible to the cinematograph were discussed. If photographs of a germinating seed were taken by the cinematograph at regular intervals during many days until the seed had germinated and sent up its seed leaves, the photographs could be thrown on the screen and spectators could see the earth raised up by the swelling seed, the seed-coat thrown off, the seed leaves emerge, straighten themselves out, and then the first leaves burst forth. The lecturer's first experiments were made with a film cinematograph, but there were defects, as the celluloid film would not stand the damp of the greenhouse. More successful were her experiments with the kammatograph, in which the photographs are taken on a glass disc instead of a film. The disc, 12 inches in diameter, was suspended in a metal ring; it was coated with a sensitive emulsion, just like any

ordinary photographic plate, from which it only differs in size, and was capable of taking 350 photographs. When ready for use, the disc was put into the machine, which was light-proof, and by means of a handle at the side could be rotated, so that every part of the plate was exposed before the small oblong opening in front of the lens and the photographs appeared in a spiral on the disc. In many stages of the process a photograph taken once every quarter of an hour was found sufficient. The practical difficulties in this kind of photography were explained by the lecturer, who showed on the screen some very beautiful examples of her work with the *sparmannia africana*, the weather plant, and the sensitive plant (*mimosa sensitiva*). Mrs. Scott apologised for some imperfections in the photographs, but after three years' work she had only eight successful plates. Her hope was that in course of time the machine might be made automatic, so that the photographs could be taken at night as well as by day.

PRINTING PROOFS IN BROMIDE.

WHEN only one print has to be made from each of several negatives, much time and paper may be wasted, even by the experienced printer, through errors in exposure, although the density of the negatives may be fairly alike; and, of course, still more will be lost when there are great differences in the densities of the plates. Mr. Harold Baker, writing in "Photographic Scraps," says:—

"No doubt waste may be prevented by cutting a sheet of paper into strips and making a trial exposure, but this is a 'counsel of perfection' to which few will attain, except, perhaps, when working large sizes. Another objection is that such a method takes more time."

A Preventative of Waste.

A good plan is to have two dishes of developer, one normal, of say a mixture of hydroquinone and metol, and the other containing a developer of metol only. When about to print, each negative should be carefully examined for density, not forgetting colour also, as a slight yellow stain has far more light-stopping power by artificial light than by daylight. If the negative is hard, or dense, or yellow, the exposure must be long, and development should be begun in the dish containing metol developer only.

If the image should flash up very quickly or show signs of being too flat, the print should at once be removed from the metol and be placed, without washing, in the dish of mixed developer, with a good rocking to wash out any metol developer remaining in the print. Beautiful vigorous prints with good half-tones may be secured in this way.

Negatives of Different Densities.

If the next negative has only a little more than the average density, the exposed paper should be placed in the mixed developer first, and be removed to the metol when the stage is reached at which development appears to cease. This stage will vary with different negatives and different exposures.

With some, the print may have to remain in the mixed developer until development is almost complete, being transferred to the metol to bring up the delicate tones; with others the print may need removal to the metol soon after development has begun.

It may sometimes be necessary to return the print to the dish of mixed developer before it is quite finished, if it shows signs of becoming too flat when in the metol.

No doubt all this appears troublesome, but it is not really so; and the method will often give excellent results from negatives which will not yield good prints in any other way.

Prints of Bad Colour.

I have been troubled during very cold weather by getting dirty green prints, and for a time was at a loss to account for this, until I remembered that such failures always follow on the presence of an excess of restrainer in the developer, and that cold has a powerfully retardive effect on chemical action, so that we are always recommended to use more restrainer in hot weather.

I at once reduced the amount of bromide in the developer from six drams to four, and have since had no more green prints.

Warm Developer.

I have tried, in extremely cold weather, the effect of slightly warming the developer, but if the warming is sufficient to be perceptible to the fingers, the prints are covered with patches and streaks of tiny white spots, due to small air-bells clinging to the paper.

A friend once showed me such a print which he was going to send back to the maker as bad paper, but I at once said, "You used warm developer," and he admitted that he had.

Obtaining the Best Prints.

I believe many bromide prints suffer from over-exposure and too short development. I do not think that a print should be so exposed, that at a given second it must be snatched from the developer, lest it be too dark.

In my opinion, the best prints are those which have been so exposed that they may remain in the developer some ten or twenty seconds after development appears complete, without any further apparent change taking place from the longer time.

The blacks are richer with more shadow detail, and the delicate tones are clear and full of modelling.

On the other hand, a print that has to be snatched out is apt to show rusty blacks and clogged shadows, while the delicate tones are flat and muddy.

The experience of other workers may lead them to a different conclusion, but my views are founded on my experience of printing portraits where great delicacy in the tones is essential.

I am not yet decided whether the same holds good when developing enlargements.

FOREIGN NOTES AND NEWS.

The Development of P.O.P.

THE development of collodio and gelatine chloride papers has been known for many years, but there has always been wanting a process which would give any desired tone by development alone and without the necessity of subsequent toning and fixing. Now in the "Revue de Photographie," Herr Schweitzer suggests the following method for obtaining various tones, these being also, to some extent, dependent on the exposure of the paper. If the paper is exposed till only the deep shadows are printed faintly, weak contrasts and greenish, black, or bluish tones are obtained. If the shadows are printed out, brown or purplish hues are the result; whereas if the image is fully printed out, reddish tones are obtained. The solutions are:—

A.
Saturated solution potassium bichromate.

B.
Pyrogallol 1.5 g.
Water 1,000 ccs.

		C.
Citric acid	20 g.	
Water	100 ccs.	
For use, mix as follows:—		
Greenish tones.		
Solution A	3 drops.	
Water	25 ccs.	
Increase of A produces greener tones.		
Blue-black tones.		
Solution A	1.2 drops.	
Solution C	5 drops.	
Water	25 ccs.	
Brownish-red Tones.		
Solution A	1 drop.	
Solution C	1 cc.	
Water	25 ccs.	
Plum-green Tones.		
Solution A	3 drops.	
Solution C	8 drops.	
Water	25 ccs.	
Cherry-red Tones.		
Solution A	1 drop.	
Solution C	3 ccs.	
Water	25 ccs.	

The prints should be immersed without washing in the desired bath for from 5 to 10 seconds, only then immersed in the pyrogallol solution, and when completely developed immersed in a 10 per cent. solution of sodium sulphite till the colour of the bichromate is discharged, and then fixed and washed.

In a recent number of the "Papier Zeitung," Dr. Lux gives the following formulæ for preparing the well-known ferro-prussiate paper, which do not differ from existing formulæ, except that he gives the exact quantity of sensitiser for a given area. For a very hard, smooth-surfaced, wood-pulp paper the following is recommended:—

Green ammonio-citrate of iron...	1,000 g.
Water	2,000 ccs.
Potassium ferriyanide	333 g.
Water	1,000 ccs.
Dextrine	100 g.
Water	1,000 ccs.
Potassium bichromate	1 g.
Water	10 ccs.

The dextrine is used to obtain sufficient sensitising solution on the surface, and the bichromate makes it insoluble. The above quantity of solution is the correct quantity for from 500 to 600 sq. cm. For very soft paper, with plenty of linen, the sensitiser should be:—

Green ammonio-citrate	1,000 g.
Water	2,000 ccs.
Potassium ferriyanide	333 g.
Water	6,000 ccs.

Papers prepared with these solutions will keep for a month; if 10 g. of oxalic acid be added a more sensitive surface is obtained, but the papers do not keep so long.

Photo-Mechanical Notes.

THE EXHIBITION OF PROCESS-ENGRAVING AT SOUTH KENSINGTON.

II.

ANOTHER careful survey of the exhibition convinces us that the really interesting part of the show lies in the historical section. The modern work is of almost uniform excellence, an excellence apparently produced by the same or similar methods. Thus in photogravure every firm's work would seem to be produced by the Talbot Klic method, and with the exception of the fine machine-printed plates shown by The Rembrandt Photogravure Company, which will bear comparison with many of the hand-printed proofs shown, and the rather flat intaglio half-tones shown as Meisengravure, there are no novelties in the photogravure work. It is remarkable that more work is not turned out machine printed. We believe this is perfectly feasible as we have been shown such proofs from ordinary photogravure plates without any mechanical grain that would be difficult to distinguish from hand-proved plates, and this ought to make small editions of small plates considerably more popular.

The English photogravure work will certainly bear comparison with the foreign both for size and quality; indeed, we fancy that the coloured photogravure of Her late Majesty Queen Victoria by the Art Photogravure Company is the largest picture in the exhibition. There are a large number of coloured photogravures shown, most of them being produced by the process explained by Mr. Herbst some years ago at the R. P. S., which consists of a single photogravure plate rather heavily coated being inked up in different colours by means of little sponges or leather dabbers, and then the whole being printed at the operation. Some exceedingly dainty work of this character shown by Messrs. Manzi, Joyant et Cie. But there are shown

also, some printed from separate plates, notably one from Messrs. Chauvet et Cie., of Paris, which shows a coloured photogravure in four printings and the single impressions in the four colours which build up the final proof. For small work one would think that this was an economical way of producing coloured photogravures for which there should be some demand, as something superior to coloured half-tones or collotypes.

Similarly in photo-lithography the historical section is the most interesting, for here we see beautiful results by all sorts of methods, the most striking being the grain work shown. All lithographers and photo-lithographic experimenters ought to see this; it might deter some of them from patenting or offering as valuable secrets obsolete processes. The novelty here is the application of the cross line screen to photo-lithography, as in Clamp and Wilbert's three colour, the Algraphy exhibit and several others, or in the large work shown by the State Printing Office of Vienna or in simplest form by the Meisenbach poster of the "Cherry Girl," a form of gigantography apparently similar to the posters produced by one or two firms of lithographers, with which we have been familiar for some time. The most remarkable photo-lithography is the work of the Polygraphisches Institute, printing from colour-selected negatives on to a bitumen-covered stone or zinc, the nature of the bitumen solution causing it to reticulate after exposure and development. Some fine flower studies are shown, and also some portraits together with the originals. A similar process is that of Messrs. Bruce and Co. We miss the fine work of Unie, in Prague, which is also a reticulating bitumen process.

There is not so much collotype work as one would have expected. Messrs. Wertherman have the principal show on the English side, with many good-sized plates, some in monochrome and some coloured. There is much coloured collotype work from abroad, in three and more colours, and collotype in combination with lithography; the Vienna State Printing Press sending a magnificent proof forty inches in width from a painting of a country lane in autumn, a collotype transferred to stone supplemented by colour printings from lithographic stones, and attention should also be paid to the magnificent facsimiles of old illuminated manuscripts by this method shown by the Berlin State Printing Office.

With regard to the remaining processes, there is not much to say, there is hardly anything connected with half-tone in the historical section, and while perhaps the largest number of exhibits are three and four-colour half-tones, there is little that is new to be seen. The English display is quite excellent, though but few firms are showing; Messrs. André and Sleigh, Hentschel Colourtype and Swain, being the most prominent. The Polytechnic show some three colours as well as "irradiation" studies; the L.C.C. School of Photo-Engraving have a conspicuous exhibit which endeavours to give some idea of the operations involved not only in three colour, but in collotype and photogravure also, showing the materials used, as well as several specimens of work executed at the school.

There are some fine four colours from Dr. Albert, and Angerer and Göschl, and a good show from Messrs. Malvaux, of Belgium, and others too numerous to mention. The American exhibit, which one would have expected to be particularly fine, does not amount to very much except for the very nice proofs of difficult subjects sent by Mr. Ives.

We understand that the Exhibition remains open for some months.

Varnish in Printing Inks.

An important point in connection with three-colour printing is the vehicle in which the colour is distributed. A powder colour is always much lighter than one mixed with a vehicle, and the higher the refractive index of the varnish or vehicle the deeper the colour, till when the refractive index is the same as that of the powder the

maximum depth is obtained. This, as pointed out in the "Zeitschrift für Reproduktionstechnik," is well seen in the case of oil and water colours; because in the former case the vehicle is not entirely volatilised, but partly oxidised to a resin. Arguing from this, it is obvious that an ink will appear less saturated and less brilliant the less vehicle it contains, or the more this evaporates or is soaked up by the paper, and therefore absorbent, quickly-drying papers never give such brilliant results as hard-surfaced papers. Inks, too, which contain a lot of turpentine give less brilliant results than those which contain much varnish. In trichromatic printing, although the three inks may be absolutely equal in saturation and brilliancy, yet that first printed will always be less brilliant than the others because its vehicle is absorbed more by the paper, and that colour printed last must always be the most saturated and brilliant because it is practically printed on a varnish formed by the other inks.

The Schumacher Vignette Stop.

The accompanying illustration shows this new half-tone stop, which has been patented by Klimsch and Co., and is reproduced from an article by Herr Mente in the current number of the "Zeitschrift für Reproduktionstechnik," and to which reference was made in this column on p. 190. The chief advantages claimed are

the shortening of time of exposure and a more correct rendering of the scale of gradation, which is alterable by alteration of the screen distance.

A patent (No. 4,764) was applied for on March 7 "for improvements relating to the etching of printing plates," by W. G. Thorpe, 7, Southampton Buildings, Chancery Lane, London. (Date applied for under Patents Act, 1901, March 8, 1904, being date of application in United States.)

THE "Record" Exposure Note Book is the latest claimant for favour among photographers who conduct their operations on systematic lines. It has been designed by Mr. J. H. Baldock, F.C.S., secretary of the Photographic Section of the Croydon Natural History and Scientific Society, and well-known for his photographs in record work. The plan of the book is novel, and takes the form of a number of separate leaves held together in a neat cover. These leaves are perforated for detachment, and space is provided for data of stop, light, focal length of lens, compass point, date, time of day, exposure, and other facts likely to prove useful to all those who seriously go in for record and survey work in various counties, and who have felt at times the want of space in their exposure note book to record full particulars of their negatives. The leaves can be either taken out and tied up together, or pasted on to the envelopes containing the negatives, as they are very thin, but strong. The books, which are copyright, sell at 1s. each for 100 exposures. Loose leaves are 1s. per 100 for 200 exposures, and are obtainable from most dealers or direct from Mr. Baldock, 3, St. Leonard's Road, Croydon, Surrey.

Exhibitions.

CRIPPLEGATE.

THE sixth annual exhibition of the Cripplegate Photographic Society was opened at the Cripplegate Institute, Golden Lane, London, on Monday last. This City society, which is seemingly in an agreeably flourishing condition, is to be congratulated on its environment, and the excellent accommodation it has secured for the annual show.

Not only has the society admirable rooms for the use of its members; but the arrangements made in the central hall of the Institute for the exhibition are all that can be desired.

Sweet music is discoursed during the afternoons and evenings by the London Viennese Band; and the well-stocked stalls of Messrs. Houghtons, Ltd., Thos. Illingworth and Co., Burroughs Wellcome and Co., A. and M. Zimmermann, The Cresto Co., Keystone View Co., and Photo. Supplies, Ltd., come in for nearly as much attention as the pictures themselves.

Over 400 pictures are on view, and they include not only a great number of well-known works, but many new pictures are also to be seen. They are well and tastefully hung on screens around the walls of the room; and special praise may be accorded to the way in which the lighting arrangements at night have been installed. Not only are the frames well illuminated by a series of incandescent electric lights, but the lamps are shielded from the eyes of the visitors.

Each evening exhibitions of the prize lantern slides are given, and also demonstrations of carbon, platinotype, bromide, and ozotype printing. A loan collection of obsolete photographic apparatus is also a feature.

The awards, which take the form of plaques designed by Messrs. Burroughs, Wellcome, and Co., were made by Messrs. Reginald Craigie, A. Horsley Hinton, and James A. Sinclair:—

Class A—Champion Picture: Silver plaque, W. A. I. Hensler, "Reflections."

Class B—Portraiture and Figure Studies: Silver plaque, L. Dick, "Simple Simon"; bronze plaque, Graystone Bird, "Childhood Joy."

Class C—Landscape, etc.: Silver plaque, E. W. Taylor, "With the Breeze"; bronze plaque, J. B. Johnston, "Wanderers."

Class D—Architecture: Silver plaque, E. R. Ivatts, "Sunshine in the Old Street"; bronze plaque, J. S. Daniels, "Where the Mighty Sleep."

Class E—Lantern Slides: Silver plaque, Robert Burnie, "White Currants"; bronze plaque, H. Wormleighton, "N. Choir, Ely."

Class F—Any Subject: Bronze plaque, W. W. Palmer, "Evening Mists and Mountain Torrents."

MEMBERS' CLASSES.

Class G—Landscapes, etc.: Silver plaque, Bertram C. Wickison, "On the Surrey Hills"; bronze plaque, H. G. Stollard, "A Sussex Lane"; highly commended, G. H. King, "On the Rother." Class H—Any Subject not included in Class G: Silver plaque, J. E. Bowmaker, "To West Door, Lincoln"; bronze plaque, W. J. Hann, "A Boro' Fish Stall"; highly commended, E. W. Butler, "Chrysanthemums." Class J—Lantern Slides: Silver medal, G. H. King, "Country Road." Class K—Any Subject (for members who have not previously taken an award): Bronze medal, E. W. Butler, "Daffodils."

COVENTRY.

On Thursday evening, Mr. J. Bill opened, at the Municipal School of Art, in Ford Street, the annual exhibition of the Coventry Photographic Club. The following is a list of awards:—

For the best picture in the exhibition: Silver medal, "A bit of Old Coventry," H. D. Waters.

Class A (Landscape, Seascape, and River Scenery): Bronze medal, "Mentone," H. Rotherham; certificate of honour, "Winter Sunshine," W. Riley; honorary mention, "The High Tor, Matlock," E. H. Cooke; "Seasonable," W. H. McLaughlan.

Class B (Architectural Subjects): Bronze medal, "The Griffin," A. W. Hoare; certificate of honour, "Butcher Row," A. B. Clarke; hon. mention, "Flecked with Sunshine," W. Riley.

Class C (Portraiture and Genre Subjects): Bronze medal, "Five Stones," E. H. Cooke; certificate of honour, "Granny," J. I. Bates; hon. mention, "A Fisher Boy," F. E. Pierson.

Class D (Lantern Slides, sets of four): Bronze medal, W. Riley; certificate of honour, A. Seymour; hon. mention, H. J. Goodwin.

Class E (Passe Partouts): Prize, "A Woodland Vista," A. W. Hoare; certificate of merit, "Poppies," H. J. Goodwin.

Class F (Postcards): Prize, E. H. Cooke.

The judge was Mr. W. T. Greatbatch, F.R.P.S.

EARL'S COURT.

A photographic and picture postcard exhibition is now being held in the spacious Prince's Hall at Earl's Court, and will remain open until the 30th inst. Postcards are far more numerous than photographic apparatus, but among the latter will be found the stalls of Penrose and Co., who demonstrate the Sinop process, Barclay and Sons, Ltd., Photolinol, Ltd., and Metotype Co., Carl Zeiss, and the Quincey Photographic Development Company. Interesting professional work is shown by Ellis and Walery, Stereoscopic Company, Sturats, of Brompton Road, C. Vandyk, W. S. Campbell, W. D. Downey, P. Lankester and Co., Aerograph Company, and J. Ellsworth Gross, of Chicago, who exhibits some excellent specimens of photographs taken for advertisements, a branch of work more popular in America than in England. Among the photographic postcard dealers are E. Bamforth, whose representative, Mr. J. E. Rushworth, shows some very fine examples of illustrated songs, etc., from life models; Wrench and Co., and Raphael Tuck and Sons, who have nearly fifty thousand different designs. The Photochrom Company, Wharton and Co., Carl Hentschel, Ltd., John Swain, and W. J. Bruce and Co. also have very attractive exhibits. A series of chromolithograph cards, reproduced from pictures in the world's galleries, are displayed by Messrs. Minch and Stocks.

FORTHCOMING EXHIBITIONS.

March 16-30.—International Photographic Exhibition, Earl's Court. The Organising Managers, 119-125, Finsbury Pavement, London, E.C.

March 27-April 1.—Leicester and Leicestershire Photographic Society. Entries close on March 20, 1905. Secretary, R. Warden Harvey, Oriental Cafe, Market Place, Leicester.

March 30-April 3.—Chiswick Camera Club. H. Gentry, 39, Fairfax Road, Chiswick.

April.—International Exhibition, Genoa. Sec. Gen., Piazza Montane Marose 18, Genoa.

April 3-15.—Photographic Society of Ireland. Hon. Secretary, R. Benson, 35, Molesworth Street, Dublin.

April 4-6.—Wallington Camera Club. Hon. Secretary, J. W. Orbett, Nithsdale, Onslow Gardens, Wallington.

April 5-8.—Nottingham Camera Club. Hon. Secretary, S. W. B. Lines, 102, Woodborough Road, Nottingham.

April 7-15.—Photographic Trade Exhibition, Portman Rooms, Baker Street, London, W. Manager Pictorial Section, W. Selfe, 70, Dragon Road, Hackney, London, N.E.

April 7-May 8.—International Artistic Exhibition, Berlin. Director, Herr Franz Goerke, Maassenstrasse 32, Berlin, W.

April 24-29.—Redcar and Coatham Literary Institute Photographic Society. Secretary, W. Hildrith, 42, Newcomen Street, Redcar, Yorks.

April 27-29.—Southend-on-Sea Photographic Society. Hon. Sec., J. Archer, 24, Ashburnham Road, Southend-on-Sea.

April 28-29.—Watford Photographic Society. Hon. Secretary, C. J. Trevarthen Ashcroft, Bushey Hall Road, Watford.

May 1-31.—International Exhibition of Photographic Pictures Postcards, concurrently with the 10th Salon. M. le Secrétaire Général du Photo Club de Paris, 44, Rue des Mathurins, Paris.

May 9-10.—Ballarat Camera Club. Hon. Secretary, G. Montgomery, 201, Sturt Street, Ballarat.

May 10 to June 19.—Salon of the Photo Club de Paris. Entries close March 1, and pictures must arrive by April 10. Secretary, Paul Bourgeois, 44, Rue des Mathurins, Paris.

June.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

FORTHCOMING COMPETITIONS.

March 31.—Ilford. £750 in cash prizes for negatives on Ilford plates. Ilford, Limited, Ilford, E.

September.—Kodak. £400 in prizes for results on Kodak products. Kodak, Ltd., 57-61, Clerkenwell Road, London, E.C.

THE DUBLIN CONVENTION.

THE preliminary announcement and programme of the Twentieth Annual Photographic Convention, to be held at Dublin in July next, have been published, and the arrangements portend a very successful meeting. This is the second occasion on which Dublin has been chosen as the venue of the convention, and, given fine weather, there is no reason to doubt that the gathering will prove as enjoyable and useful as that in 1894, when Sir Howard Grubb was president. The president on the present occasion is Professor John Joly, F.R.S., D.Sc., and the following is the programme of arrangements:—

Monday, July 10 (Morning and Afternoon).—Conducted parties to places of interest in and around the city (Phoenix Park, Guinness' Brewery, Killiney Hill, etc.). 7.30.—Official reception by the president at the Royal Dublin Society's Buildings, Kildare Street. 8.—Presidential address in the new Lecture Theatre, after which there will be a conversazione in the Museum Buildings adjoining.

Tuesday, July 11.—Excursion to the Vale of Glendalough and the Seven Churches. There will be no meeting in the evening.

Wednesday, July 12.—Morning at 10.—Annual general meeting. At 11.—Meeting of the New Council. Afternoon.—Sir Howard and Lady Grubb will give a garden party and reception at the Zoological Gardens. Evening at 7.—Annual dinner and smoking concert at the Gresham Hotel.

Thursday, July 13.—Excursion to Bray (the Brighton of Ireland) and the Dargle, one of the most romantic and charming glens in the county of Wicklow. Evening at 8.30.—At Trinity College, an illustrated lecture by Dr. E. MacDowell Cosgrave, on "Old Dublin."

Friday, July 14.—Excursion to Drogheda, Monasterboice (with its far-famed Celtic crosses) and Mellifont Abbey, the earliest Cistercian Abbey founded in Ireland. Evening at 8.30.—At Trinity College, a paper or demonstration.

Saturday, July 15.—Excursion to the Hill of Howth, its rocks and demesne.

General Arrangements.

Place of Meeting.—By the courtesy of the Board of Trinity College, the ordinary meetings during the week will be held in the Engineering School of that historic building, and by kind permission of the Royal Dublin Society and the Museum authorities, the reception and conversazione will take place in the new Lecture Theatre of the society and the magnificent Museum Buildings adjoining.

Trade Exhibition.—The Trade Exhibition of apparatus, pictures, etc., will be in Leinster Hall, Molesworth Street, about three minutes from Trinity College.

Excursions.—It is anticipated that in July, cheap excursions to Ireland will be running from all parts of the kingdom; and return tickets at single fares will be issued by all the Irish railway companies to members during their visit to Ireland.

Accommodation, etc.—For further particulars of excursions, hotels, private apartments, dark rooms, dealers, etc., etc., see the official illustrated handbook, which will be issued to members as soon as possible.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents were made between March 6 and March 11:—

FOLDING CAMERA. No. 4,831. "An improved folding photographic camera." Emile Pipon, 5, John Dalton Street, Manchester.

CAMERAS.—No. 4,874. "Improvements in photographic cameras." J. Ebenezer Bousfield, 4, South Street, Finsbury, London, for La Société du Photochrome, France.

MERCURY LAMPS.—No. 4,867. "Improvements in lamps known as electric vapour lamps, or mercury vapour arc lamps, or hermetically enclosed arc lamps." Charles Orme Bastian and George Calvert, Birkbeck Bank Chambers, Chancery Lane, London.

LENSES.—No. 4,868. "Means of reducing the amount of light passing through a lens without decreasing its rapidity for photographic purposes." William Rice, Birkbeck Bank Chambers, Chancery Lane, London.

X RAYS.—No. 4,939. "An adjustable diaphragm for X-ray photography and other mechanical appliances." Henry Burgess, 50, Crowther Road, South Norwood, London.

FLASH POWDERS.—No. 4,964. "New flashlight powders." H. E. Newton, 6, Bream's Buildings, Chancery Lane, London (Farbenfabriken vorm. F. Bayer and Co., Germany).

CALCULATORS.—No. 5,109. "Improvements in calculating slide-rules for opticians, photographers, and the like." Alfred Salomon, 32, John William Street, Huddersfield.

BOLTON Amateur Photographic Society.—In connection with this Society we are desired to announce that a change of secretaries has taken place, and that the present secretary is Mr. John Wild, of 9, Infirmary Street, Bolton, to whom all future communications should be addressed.

A FORGED ORDER.—At the Birmingham Assizes, on Monday last, George Burlace, 21, painter, was indicted for forging and uttering an order for the delivery of a folding pocket kodak. On behalf of Messrs. Gibson, Gooch Street, he had obtained goods from Messrs. Hurman. On January 23 he appeared at Messrs. Hurman's with a forged order purporting to come from Messrs. Gibson. He received the goods, and subsequently pawned them, Prisoner was found guilty.

RUSTIC SIMPLICITY.—It is hard to believe that the most unsophisticated countryman would stand for five minutes before a dummy camera, with no slide or plates, under the impression that he was having his photograph taken, and pay 1s. 6d. for a promise that the photographs would be sent in a fortnight at most. But so many people were thus defrauded by two Ipswich men named Kerby that at Needham Market Petty Sessions they were summarily sentenced to a month's hard labour. A list of eighty-six victims was produced in court, and £9 18s. was their aggregate loss. The camera, said a witness, was "an egg without a yolk."

New Apparatus, &c.

"Cooke" Series II. and Series IV. Lenses. Made by Taylor, Taylor and Hobson, Stoughton Street Works, Leicester.

These two new series of Cooke lenses are designed, as we have already mentioned, for high-speed photography, portraiture, and for the many occasions where critical definition at a large aperture over a considerable angle is required. The Series II. are designed to work at F/4.5, and the Series IV. at F/5.6. In construction, both series resemble the well-known Cooke lens, each consisting of three single glasses, a distinctive type, to which the makers ascribe rapidly over and above that of complex lens systems of the same nominal aperture. The image in each case on the focussing screen is beautifully sharp and brilliant; but, in order to obtain authoritative and delicate tests of the flatness of field and its anastigmatic correction, we append determinations made by the Department of Technical Optics of the Northampton Institute. As a standard of correction of these aberrations, Mr. S. D. Chalmers, the director of the department, adopts the following:—"The corrections are considered sufficient when (1) the astigmatic difference and (2) the departure of the image from the plane of the plate does not exceed 1mm. for each 100mm. focal length." Perhaps the English reader will grasp the degree of correction which this represents if we convert it into British measures:—1mm. in 100mm. is the same thing as 1-20th of an inch for a 5-in. lens. We can now state the results as measured:—

Cooke Lens. Series II. F/4.5. Eight inches focal length.

Semi-angular Field.	Correction of astigmatism and curvature of field at full aperture, F/4.5.	
Degrees.	Astigmatism.	Curvature
0	0.0	0.0
5	0.2	—0.1
10	1.0	—0.2
15	1.7	—0.4
20	.2	1.7

"Note.—The lens is excellently corrected up to 21 deg., covering a length of plate of 6 in. for a distant object. It falls off a little up to 6½ in., and then falls off very rapidly. For nearer objects the plate well covered would be slightly greater."

Perhaps the reader will not realise at once the practical meaning of these figures. Therefore we may point out that the greatest deviation of the field of the lens from the flat plate with which it should coincide is 1.7mm., or 1-16 of an inch, and this at the extreme edge of the plate. This flatness of field, it need hardly be said, is very satisfactory indeed in conjunction with the correction of astigmatism, which does not exceed the figure for curvature. We are not guilty of exaggeration in describing such an anastigmatic field as that of a lens of highly perfected manufacture. Messrs. Taylor, Taylor, and Hobson's special claim for these lenses is fine definition over a useful angle, and that we can say they have accomplished in the most successful manner.

The Northampton results with the Series IV. lens (8 in. focal length) are as follows:—

Semi-angular Field.	Astigmatism.	Curvature.
Degrees.	mm.	mm.
0	0	0
5	.2	.1
10	.8	.1
15	1.0	.0
20	.4	— .8
22	2.4	— 2.3

"The lens is excellently corrected up to 20 deg., covering a length of plate of 6 in. The definition is very good up to this point, falls off slightly up to a plate-length of 6½ in., the plate specified, but does not cover the corners of this plate at all satisfactorily."

We have thought it well to state frankly these measurements in order to give Messrs. Taylor, Taylor, and Hobson the opportunity to demonstrate the properties of the lens—which they do in a negative of a test chart representing the definition across the diagonal of the half-plate, and we must confess that the definition is excellent, almost up to the corner. Possibly the Northampton test outruns the delicacy of the test object method of testing; but whether that is so or not, we are confident that the flatness of field does not suffer a departure from truth great enough to be discovered in practice with cameras as commonly manufactured. In other words, we regard the two new lenses as possessing very strong claims upon the notice of photographers, and as making possible extremely fine work on every occasion when a large aperture is to be used.

Such a method of review as we have here adopted is, by its very nature, unfortunate, in that it states the errors and not the perfections of the lens, and unless the reader will study the figures as indications of the closeness with which the lens approaches the ideal in performance, he may be misled by them. Especially desirable is it in accepting such evidence of the quality of a lens, to have at hand data relating to the other instruments under comparison: for optical perfection is relative, not absolute, and the difference between lenses—often great, it is true—is nevertheless one of degree.

These new lenses, and all the other optical manufactures of Messrs. Taylor, Taylor, and Hobson, are described in the new catalogue issued this week, and containing the little treatise, "The Principles of a Lens's Action," to which we have several times referred those anxious to obtain a clear and concise statement of the factors which enter into the construction and use of a lens.

The Bi-metric Minimeter. Supplied by Parke, Davis, and Co., 111, Queen Victoria Street, London, E.C.

A most convenient measuring device for the dark-room is supplied under this formidable name. The tube is graduated into minims and tenths of a cubic centimetre, so that the relative value of the

two measures is seen at a glance. The liquid can be delivered rapidly by opening a valve in the bulb, or drop by drop, with the utmost precision, by closing the valve and pressing the bulb.

Photo P.O.P. Made by the Rotary Photographic Co., Ltd., 12, New Union Street, Moorfields, London, E.C.

The addition of a gelatine printing-out paper to the list of "Rotograph" manufactures is a step which the Rotary Company are fortunate in being able to take with the knowledge that the new material will not suffer, but will gain, from association with the arm's bromide and gaslight papers. The new "Roto" paper makes one special claim to a place among the many papers of the P.O.P. class—it can be worked without an alum bath, even in hot weather, by reason of the

hardness of its surface. Prints may thus be trimmed before toning, and will not tear or acquire frayed or damaged edges during toning and the after processes. In regard to this claim, we can say that we have soaked prints on the paper in water at 80 deg. F., and found the gelatine surface to remain hard and firm when rubbed with the finger. It was equally firm after five hours' soaking in the water, as it gradually cooled to 65 deg. F. This fact will prove the great immunity of the paper to warm solutions; and practically substantiates the makers' claims on its behalf. Further than this, we have made prints in the "separate" sulphocyanide bath without the use of alum at any stage in the process, and on soaking these prints at last in water from 70 deg. to 80 deg. Fahr. before squeezeing, they stripped off in the usual manner. These results are sufficient to show that the paper is able to withstand the ordinary differences in the temperature of solutions, and for this reason alone it is entitled to the consideration of photographers. For the rest, it is a P.O.P. of excellent printing quality, and tones well in the separate or combined bath.

A REVISED catalogue of the colour-measuring instruments made by the Tintometer Limited reaches us from the Colour Laboratories, Salisbury.

The annual report of the Sussex Archaeological Society contains the information that 330 prints had been received in connection with the photographic survey of the county. The majority of the prints are from old photographs.

THE Harmsworth Encyclopædia, now appearing in forty fortnightly parts at 7d. each, is a triumph of popular educational literature. "Everybody's book of reference" is the publisher's own description of it, and the first part is certainly an assurance that the possessor of the complete work will have at hand a fund of information on every conceivable subject.

PIONEER Work in Siberia.—A lecture of considerable interest was delivered in the Foresters' Hall, Dundee, last Tuesday, by Mr. S. Turner, under the auspices of the Dundee Branch of the Royal Scottish Geographical Society, entitled "Travelling, Exploration, and Climbing in the Siberian Mountains." Mr. Turner made a winter journey of 10,000 miles to the wild and silent district in which the great Altai range stands; and he is the first European who has ever entered upon such a dangerous exploring and climbing expedition. Mr. Turner's lecture was convincingly illustrated by a series of excellent photographs taken by himself.

An electrical exhibition is now open at 118 and 122 High Holborn, London, W.C., and will remain open until April 5. It is brought together under the auspices of the County of London Electric Supply Company, and though the greater number of the stall holders are firms catering for electrical mechanicians and others in the electrical world, there are several exhibits of interest to photographers. The charge for admission is only sixpence, so that anyone who is in the neighbourhood might well arrange to pay a visit to the show, which is unique in one way, namely, that it is held in temporary buildings erected underneath the large scaffoldings on which an army of bricklayers are at work on the new block for Messrs. Gamage. Messrs. Penrose, of 109, Farringdon Road, London, E.C., exhibit the Cooper Hewitt mercury-vapour lamp, with a number of electrical motors for driving small wood-working and other machinery. The Westminster Engineering Company, of Victoria Road, Willesden Junction, show enclosed arc lamps for which they claim special features in photographic portraiture and for photo-engraving. A novel form of incandescent lighting is the "Linolite," a filament lamp made in long narrow cylinders provided with aluminium reflectors. It should be particularly well suited to photographers' window and reception-room decoration, though it is not advanced as a studio light. Its exploiters are the Linolite Co., 25, Victoria Street, London, S.W.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

March.	Name of Society.	Subject.
24.....	Aberdeen Photo. Association	Exhibition of Slides. Mr. Tennant.
24.....	Wimbledon and Dis. Cam. Club	<i>Pigment Stripping Film for Three Colour Photography.</i> Demonstrated. Mr. W. A. Sims.
24.....	Edinburgh Photographic Soc.	<i>A Large Aperture.</i> Illustrated. Mr. F. C. Wardall.
27.....	Wakefield Photo. Society	Annual Lantern Exhibition.
27.....	Motherwell Y.M.I. Cam. Club	<i>Woodlands.</i> Mr. Dan Dunlop.
27.....	Southampton Camera Club	<i>History of Painting.</i> Illustrated. Mr. W. R. Kay.
28.....	Royal Photographic Society	<i>Cameras and other Apparatus for Three Colour-Work (with models).</i> Mr. W. Gamble.
28.....	Border City Camera Club	<i>Trip to London.</i>
28.....	Perthshire Soc. of Nat. Science	<i>Exposure and Development.</i> Demonstrated.
28.....	Monklands Photo. Society	Members' Lantern Slide Competition.
28.....	Bristol Photographic Club	Exhibition of Lantern Slides. Mr. W. Aver Duncan.
28.....	Nelson Photographic Society	<i>Photo-Micrography.</i> Demonstrated. Dr. Bird.
28.....	Glasgow Southern Photo. Assn.	<i>Woodland Photography.</i> Mr. Dan Dunlop.
28.....	Devonport Camera Club	<i>Stripping Pigment Films (for Three and Single Colour Photography).</i> Demonstrated. Mr. W. A. Sims.
28.....	Birmingham Photo. Society	<i>Cloud Negatives and Printing.</i> Mr. H. W. Bennett, F.R.P.S.
29.....	G.E.R. Mechanics' Institution	Lantern Evening. Mr. A. Woolford.
29.....	Photographic Club	<i>Home Portraiture with Lantern.</i> Mrs. W. D. Welford.
29.....	Boro' Poly. Photo. Society	Second Social Evening.
29.....	North Middlesex Photo. Society	Technical Meeting.
29.....	Central Photographic Society	<i>How the Window Greiv.</i> Mr. E. W. Harvey Piper.
30.....	Shotts Camera Club	Exhibition Opens.
30.....	Gateshead Camera Club	Exhibition of Members' Lantern Slides.
30.....	L.C.C. Sch. of Pho.-Engraving	<i>Harmony and Contrast in Colour Mixing.</i> Mr. C. G. Zander.
30.....	Richmond Camera Club	Lantern Slides—A Series by Mr. O. G. Rejlander, lent by the Royal Photographic Society.
30.....	London and Prov. Photo. Assn.	<i>St. Louis.</i> Mr. E. P. Drage.
30.....	Liverpool Amateur Ph. Assn.	<i>Morocco.</i> Mr. Harry Mahler.
30.....	Glasgow Eastern A.P.A.	"A. P." Prize Slides.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

It has been arranged by the Committee to hold an informal dinner, at which they will be pleased to see any members who may choose to join the party, at the Villa-Villa Restaurant, 37-38, Gerrard Street, Shaftesbury Avenue, W., on Friday, March 31, at seven o'clock. Morning dress. The price of the dinner will be 2s. 6d. Members desiring to attend should communicate their intention to the Hon. Secretary, 51, Baker Street, W., not later than Tuesday the 28th inst.

ROTHERHAM PHOTOGRAPHIC SOCIETY.—At a meeting of this society, held in the St. George's Hall, Rotherham, on Wednesday evening of last week. Mr. J. W. Charlesworth, of Sheffield, gave an illustrated lecture on "Orthochromatic Photography." He explained how ordinary plates did not sufficiently distinguish the luminous value of blue sky from that of white clouds, and how the greens and reds of our landscapes received no adequate representation on the plate. He also showed how in photographing flowers a brilliant red or bright yellow will often show as a dark patch on the print, while a deep blue will be represented as nearly white. To illustrate this more fully, the lecturer had made special lantern slides composed of a group of iris, pinks, cornflowers, narcissus, one slide being made from a negative on an ordinary plate, another from one on an orthochromatic one, and still another on an ortho plate with an iso screen. The differences were so great as to leave no doubt that an iso-screened chromatic plate was much superior to an ordinary, where colour luminosity was essential. The lecturer strongly urged the absolute necessity of using an iso screen when employing orthochromatic plates, or the results would be disappointing. His slides fully justified these remarks, and many of the sunlight effects which

he showed were obtained by this process. He claimed also that distance and atmosphere were not lost when using the screen. In order to effectively display the numerous comparison slides made by the lecturer, two lanterns, side by side, were brought into use.

CAMBRIDGE PHOTOGRAPHIC CLUB.—A lecture on "Process Work" was given before the members of this club on Monday of last week by Mr. William Gamble. The lecturer explained that "process" was a generic term for all kinds of processes produced by photographic methods. The processes of reproducing pen and ink line drawings, maps, prints, etc., by the line zincographic method; the half-tone process for reproducing photographs, wash drawings, and natural objects; the photogravure process for reproducing paintings and other works of art; the collotype process for reproducing photographs without offensive mechanical grain; the "ink photo" and other processes of photo lithography, and the three-colour process, were all fully described and illustrated by means of lantern slides and by demonstration with plates, tools and specimens. Mr. Gamble concluded by stating we had not reached finality in these processes, and he mentioned that he had seen a machine which would engrave blocks by mechanical means in about two minutes, and what was more wonderful two of these machines might be operated by the telegraph hundreds or perhaps thousands of miles apart, one machine reproducing the work of the other, and thus it became possible to telegraph pictures. Further there were now in use in American newspaper offices etching machines which etched out half-tone plates in one minute, indeed practically equivalent to putting in the photograph at one end, and getting out a finished block at the other. With increasing facilities the tendency would be to use more and more illustrations in our newspapers and books, and when the public became surfeited with the monotony of black and white, the three-colour process would step in to give more truly the realism of nature. In the end there would be less and less need to resort to verbal descriptions. History would accordingly repeat itself, and once more the world would resort to pictorial expression, the earliest of all means of recording thought, and the most universally understandable. There would be no need for Volapuk and Esperanto so far as printed communication is concerned if nations inter-communicated by means of pictures.

GLASGOW EASTERN AMATEUR PHOTOGRAPHIC ASSOCIATION.—The annual general meeting of this association was held on Thursday, of last week, when the reports of the secretary and treasurer were given. These were highly satisfactory. The election of office-bearers for the ensuing year resulted as follows:—A. D. Inglis, hon. president; W. S. Crockett, president; John Brough and John Gillespie, vice-presidents; James Bicker, treasurer; M. Crosbie, lanternist; T. B. Kirkhope and Alex. Taylor, hon. secretaries; Council—Messrs. White, Kennedy, Black, McAllister, Robin, and Gibson. A series of practical demonstrations for beginners has been arranged for Monday evenings, commencing on 27th, and continuing till May 8. This is quite apart from the ordinary meetings of the club, which are held on Thursday evenings.

SOUTHAMPTON CAMERA CLUB.—The members of this club met on Monday evening, the 20th, for club slide competition, the subjects being "Portraiture or Figure Studies." The winner proved to be Mr. W. R. Kay, with two very excellent portrait slides; second place being taken by Mr. C. Daw. On Wednesday, the 15th inst., the club held their second annual conversazione in the Ogle Hall, the invitation being from the Committee to the members. About 150 of the members and their friends braved the extremely inclement weather, and a most enjoyable three hours was spent. A capital musical programme and exhibition of first-class slides had been prepared, and over the tea and coffee cups the social intercourse was of the heartiest description.

Correspondence.

- * * We do not undertake responsibility for the opinions expressed by our correspondents.

THE FELLOWSHIPS COMMITTEE OF THE R.P.S.

To the Editors.

Gentlemen,—I see that my name appears on the Fellowship Admissions Committee, Pictorial Section, in the list issued by the "Journal of the Royal Photographic Society." Permit me to say that this is an error, as I declined the honour of serving on the above Committee.—Yours faithfully, CHARLES F. GRINDROD.

THE SHOP AND HOUSE DUTY ACTS.

To the Editors.

Gentlemen,—I shall feel obliged if you can find space for the following matter, which seems a little unfair to photographers situated such as I am myself.

I am both a professional photographer and also a dealer, but I have not a shop front. Instead, I have a showcase in the front garden and also expose goods for sale in my premises, but these latter goods (not those in the garden showcase) do not happen to be visible from the road. I am therefore denied the benefit of the lower rating as a shop, and am charged instead the higher rate as a private house, although the premises I lease solely for the sale of photographs and materials, and do not live on the premises. I believe if I stuck one or two frames for sale in my front windows I might come within the Act, but I pride myself on the appearance of the place I suppose I must be prepared to suffer for my pride.

All I wish to point out is the absurdity of such an Act, which allows one man with a shop front the lower rate, and denies it to another who is doing a similar trade but has not the peculiar shape of front which comes within the Act.—I am, Gentlemen, yours faithfully, E. J. SANDER.

The Manor Studio, 4, Manor Road,
Stoke Newington, London, N.
March 20, 1905.

MR. STUART A. ORD MACKENZIE, of Midgham Lodge, Reading, writes:—Can you give me any information as to what has become of a portrait photographer by the name of Beethoven, whose business I believe was in Regent Street? I am anxious to get hold of a negative which he took about eight years ago, and possibly you or some of your readers may be able to help me.

MESSRS. P. LANKESTER AND CO., of 21, Grove Hill Road, Tunbridge Wells, write us that they will be pleased to send admission tickets for the Earl's Court Picture Postcard Photographic Exhibition to all bromide printers likely to be interested in the "Grabber" automatic bromide printing machine, which they have on view there. The machine is for printing bromides in large quantities, and is capable of printing 6,000 postcards per hour. The exact amount exposed is automatically wound off, and the light, which is also automatically worked, can be regulated to suit any density of negatives.

"THE PHOTOGRAPHIC PRESS" has appeared, under the editorship of Mr. Thomas Bedding, as a supplement to the "Optician," and will be issued separately at the price of one half-penny. Our latest contemporary nominates its circle of readers as "the amateur and the dealer," and it is suggested by the promoters that their policy will be towards establishing "The Photographic Press" in favour with the high-school miss and the sixth-form boy. Precisely how the bill of literary fare can be made acceptable to these young persons as well as to the photographic dealer it is difficult to foresee, but *labor omnia vincit*.

Answers to Correspondents.

- * * All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- * * Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- * * Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.
- * * For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

PHOTOGRAPHS REGISTERED:—

W. D. Moss, 24, Geddly Hill, Cirencester. Photograph of Deer in Bushey Park.
R. W. Sharp, 48, Quarry Street, Hamilton. Photograph of Masonic Temple, Cadzow Street, Hamilton.
R. G. Arnold, Stafford Street, Market Drayton, Salop. Three Photographs of F. Neilson. Photograph of Lord Audley's Cross, near Market Drayton.
J. R. Browning, 11, Bedford Circus, Exeter. Two Photographs of the New Eze Bridge.

"OWEN," "C. C.," and others.—In our next.

S. P.—We think you take a somewhat uncharitable view of the matter, and want of time may be some excuse.

DRAPE.—It is customary to have the bodice removed, and there is, as a rule, no difficulty in effecting this, particularly if a specimen print be shown. Surely your receptionist can be entrusted with the matter.

H. S. (Brandon).—Possibly it may be worth provisional protection, and you might then offer it to the makers of amateurs' supplies. You will find names and addresses in the "Almanac."

W. K. MOLESLEY.—The lens is evidently a very bad one, having spherical aberration and chromatism. We should say it is not worth while to attempt doctoring it.

"TOM HEATH."—The article has now appeared in full in "The Chemical News" for March 17. We do not undertake to answer electrical queries, but no doubt you could get a 5-volt current from your ordinary supply through a choking coil.

COPYRIGHT.—Kindly say if a printer and publisher can legally copy one of my original photos and sell in postcard form without asking my permission.—POSTCARD, BURY.

Certainly not. Turn back to the numerous replies to copyright queries in this column.

BURNISHER, ETC.—1. Is there any danger of the moisture attendant on the use of a steam-heated roller burnisher corroding the metal or otherwise proving troublesome? 2. Will the light from a ruby window falling on an enlarging easel affect the exposure of an enlargement?—PRACTICAL.

1. No, there is no chance of this, nor is it otherwise troublesome. 2. Certainly not, provided, of course, that the ruby glass or material is safe.

STUDIO.—As shown in the sketch there is too much top light, but this can be remedied by blinds to draw down. It would have been better if the side and top lights commenced another foot or so from the end; however, curtains will compensate for that. We should not re-paint the interior until you see the effect you get when the curtains and blinds are fitted. The studio is small, but we presume you do not require it for professional purposes.

PICTURE POSTCARDS.—1. You have one of two courses before you—either to send in a statement of account for goods supplied, and back it up with a County Court summons, or to send them a

solicitor's letter. In the former case it would be as well to give them, say, seven days in which to return prints or pay, and as you could take out the summons at your town at the cost of one shilling, it would probably fetch them at once. 2. You can obtain a gas governor, which would control the supply of gas; you might also use magnesium ribbon.

TROOPER.—If the light is too strong with the white blinds when the sun is shining we should recommend you to supplement them by rather light green ones on the roof, and by curtains of a similar colour on the sides. For the blinds union is as good as anything, and for the sides what is known as "art serge" would be best. We should advise you to try the effect of the curtains at the sides only first, as they will possibly get over the trouble, but much will depend upon the height of the side lights.

A POINT OF ETHICS.—Will you kindly inform me if it would be considered a fraud to sell a bromide, pasted on to a canvas, painted over in oils, as a canvas painting, and to what extent should I be liable?—**PUZZLED.**

Undoubtedly, if the painted bromide was sold as an oil painting, without it being stated that it had a photographic basis, which would be with an implied contract that it was an oil painting in the ordinary sense of the word, you would be obtaining money by fraud, and liable to prosecution.

CANADA.—Can you give me any information about Canada? Is there any demand for assistants? What are the rates of wages and chances of commencing a photography business in a small way?—**C. S. S.**

All we can say is that the general prospects in Canada are extremely bright, and that the next five years will see numbers of towns coming into existence in the Fertile Belt. There should be good opportunities for photographers who can rough it and can handle the business from first to last.

RUSTY BURNISHER.—I have a Globe burnisher, and the bright roller requires cleaning. Should be glad if you would kindly inform me the best way to do this, and what to use.—**G. H.**

The rust, unless too deeply in, may be removed by a tolerably fine-grade emery cloth, and finally polished with the finest flour emery cloth, or with flour emery and oil. The work must be done longitudinally, and evenly from end to end of the roller. If the rust is deeply in, and cannot be removed in this way, the roller should be sent to an engineer to do the needful.

BLACK SPOTS IN ENLARGEMENTS.—What is the acid used for removing black spots out of bromide enlargements, and in what manner is it applied?—**J. A. KELL.**

We are not aware of any acid being used. The usual process is to use:—Iodine, 20 gr.; potassium iodide, 30 gr.; potassium cyanide, 20 gr.; water, 1 oz. This is used with a fine camel's hair brush, and it is sometimes thickened with dextrine or glycerine. It is essential to dissolve the iodide first, then add the iodine, and then the cyanide, and enough of this should be used to form a colourless solution.

CHARGES.—Will you tell me a fair price for five whole-plate negatives and one platinum print from each of interior and exterior views of a house five miles away?—**JUSTICE.**

There are no uniform charges for photographs. Some photographers' prices are several times those of others, and we have not seen the pictures in question. Charge your ordinary prices, whatever they may be, for the work, and if not paid you can sue in the County Court, and you will no doubt recover the amount. You say that the pictures were taken under the directions of the client—that relieves you of the responsibility

as to the selection of views, and if the photographs are good we do not see that there can be any substantial defence.

RETOUCHING.—Please give me your opinion of my work.—**CYMO.**

The specimens are very fair—soft and reasonable in the working, and the likeness is generally well preserved. The touch is rather too stippled, and therefore slightly mechanical. Do not lift your pencil so much, but blend more and save time. All retouchers requesting criticism should state how long each negative took to work. This makes a considerable difference in the opinion passed, for commercially it means great deal to the retoucher as well as to the employer. Your treatment of the man is defective about the nose. The shape has been altered, and the high-lighting is insufficient to bring it forward as the most prominent feature of the face. The balance in the eyes is also weak; either increase the high light over the one pupil or reduce with the knife the strong lighting over the other. For preference increase the lighting. Attend more to the formation of the features and you should make a natural and effective retoucher; but avoid being too mechanical in the touch. See reply to "Limerick."

THEATRICAL WORK.—Would you give me the best and cheapest way of taking a photograph on the stage at a theatre? What is in your estimation, the best means of lighting? Would magnesia do, and how could it be managed? Or is there no some kind of powder that can be placed in different positions and set fire to? What are the best positions? Also, would a 10 x 8 lens, rapid rectilinear, do, and camera in dress circle above pit, right opposite the stage? And, if so, what exposure for a rapid plate?—**AMATEUR.**

All the usual stage lights should be kept going, and if an action or movement is to be represented, then magnesium flash light must be used, but if merely poses are to be taken, then it would be sufficient to use magnesium candles, which burn for a certain time. A rectilinear lens would answer, but should be used at as large an aperture as possible. The position of the camera is a matter of experiment. It may happen that the position named would be suitable, but the position should be chosen at which the group on the stage is of sufficient size on the plate. The flashlight or magnesium should be placed as nearly as possible in the same positions as the ordinary stage lights, but care must be taken not to include the light in the field of view, and they must be all fired at once. It is impossible to give the exact exposure, but for flashlight about 2 oz. of powder should be used, divided into three portions.

NOTICE.

Several replies are held over for insertion next week.

* * NOTICE TO ADVERTISERS.—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

The exhibition held in the Walker Art Gallery, Liverpool, in March and April of last year, not only presented an example of successful organisation that will be followed by photographic societies elsewhere, the publicity given the show in the city on the Mersey have done much to advance the claims of photography to a high position among the graphic arts in one of the art-loving centres of the kingdom. The organisation under the control of the Liverpool Photographic Association, the Manchester Amateur Photographic Society, and Leeds Camera Club, and this year Leeds is the venue for the show. From the particulars to hand, we gather of the endeavour of the Executive is, that the exhibition at the City Art Gallery, Leeds, from July 4 to August 12 is to add to the reputation of the "northern" competition, and thus permanently ensure the continuity of a class annual photographic exhibition alternating between the three northern cities, Liverpool, Manchester, Leeds, and doubtless a healthy rivalry will do much to keep this spirit alive. Further to our comments in last year's "Ex Cathedra" on loan collections of pictorial photographs, we note that a special feature of the exhibition will be the inclusion of the St. Louis Collection of pictorial photography, which, with the consent of various exhibitors, has been shipped *en bloc* to Leeds, will be hung in one of the galleries of the exhibition, decorations, etc., on similar lines to those which were exhibited at St. Louis. Particulars and information for intending exhibitors will be found on another page.

The International Congress of Photography.

We believe we are alone in announcing the seventeenth session of the International Congress of Photography, which will be held this year at Liège from July 19 to 25. In selecting Belgium as its rendezvous, the Congress Committee believes that it consults the convenience of those accustomed to attend the meetings, since Liège has its great exhibition open during the summer. The Association Belge de Photographie is making itself responsible for the organisation of the Congress, and the secretary, Ch. Puttemans, Palais du Midi, Brussels, will answer inquiries and enter into relations with photographers anxious to take part in the Congress. Papers to be read should be in the hands of M. Puttemans by June 15 at the latest. Aside from the technical and scientific labours to which the Congress will apply itself, excursions are arranged in the picturesque country around Liège, and a collection of pictorial photography will also be brought together in one of the halls of the exhibition. M. Puttemans desires us to make known the fact that British visitors will be accorded a hearty welcome to Belgium.

"Development Factor." The paper read by Messrs. Fergusson and Howard last month before the Royal Photographic Society, which is reprinted on another page, makes use repeatedly of an expression—"development factor"—which has been used by Mr. Watkins to express an entirely different thing. The Watkins developer factor is a multiple—the number of times the period required for the first appearance of the image must be repeated for complete development. "Development factor," as used by writers on sensitometry, such as Hurter and Driffield, Mees and Sheppard, and others, is a measure of the steepness of gradation given by a plate. Writings on time development would gain in clearness if two distinct terms could be generally adopted for these very different quantities.

Wetting the Plate Before Development.

A practical point cropped up in the discussion of Messrs. Fergusson and Howard's paper, which may be noted even by those who do not practise the time methods of development. The custom of applying the developer to the unwetted plate is an almost universal one we suppose, and photographers are confirmed in it from fear of the pinholes which not infrequently attend the preliminary soaking of the plate in water. For the sake of regularity the authors found it best to soak the plates in water first, and Mr. Howard explained that they were not troubled with pinhole markings if they permitted water from the tap to have quite violent access to the surface of the plate.

The 1905 Photographic Convention.

Last week we published the programme of arrangements for the forthcoming Photographic Convention at Dublin. We would draw the attention of intending members to the fact that the annual subscription is 5s., and the privileges of membership include invitations to the official receptions and garden party, admission to meetings, etc., and special rates for excursions. Mr. F. A. Bridge, East Lodge, Dalston Lane, London, N.E., the hon. general secretary, will be pleased to forward full particulars, or applications for membership can be made to the hon. local secretary, Mr. R. Benson, 3, Orwell Park, Rathgar, Dublin. So far as the visitors are concerned, there should be no question as to the success of the outing to the Sister Isle if the previous Dublin meeting in 1894 is taken as a criterion, and even lacking the stimulating influence of pleasant weather, we have reason to believe the welcome that will be extended to the members of the Convention by the warm-hearted sons of Erin forming the Photographic Society of Ireland and the reception and local committees, will amply compensate for any untoward demonstrations on the part of Jupiter Pluvius.

Picnics or Progress.

That the annual Photographic Conventions have come to be regarded in the light of pleasurable excursions, rather than a means of bringing forth much that is new or instructive in the way of photographic progress is something to be deplored. The occasion is the only one that presents itself during the year for bringing together for a week a body of photographers, both professional and amateur, from all parts of the kingdom, and yet we see from the Dublin programme that, with the exceptions of the presidential address and an illustrated lecture on "Old Dublin," no lectures or demonstrations are announced. It may be urged that members are too tired to attend evening meetings after a long day's excursion. The obvious remedy is to curtail the outings and increase the general interest of the lectures. The time has surely now arrived when the accumulated funds of the association can be applied to the chief purpose for which the Convention was originally called into being, especially on an occasion like the present when the claims of photography are recognised not only by the Royal Dublin Society to the extent of placing the New Lecture Theatre and Museum Buildings at the disposal of the Convention, but by the authorities of Trinity College itself, who will provide accommodation for the meetings during the week in the Engineering School of that historic building.

Discoloured Lenses.

In an "Ex Cathedra" note last week we alluded to the discolouration of the glasses of which some of the older photographic lenses were constructed. Since then we have seen a very marked example of that defect. It was a whole-plate portrait lens of the Petzval type of French make. It seemed to be a copy of a Voigtlander instrument, and was, probably, made some forty years or more ago. We say that it appeared to be a copy of a Voigtlander lens because the mounting was similar, and the aperture and focal length were, as nearly as possible, the same as that of Voigtlander's make at that period. The instrument was said to be slow, but otherwise very good, and so indeed it was. On taking it apart the cause of the slowness was at once manifest. When the flint lens of the posterior combination was laid on a piece of white paper it was seen to have a marked yellow colour; and when the anterior combination was similarly dealt with the discolouration was still more pronounced. A closer examination showed that not only had the flint

element changed, but that the balsam cement had also become very yellow. No wonder, then, that the lens was slow in action.

Coloured Lenses.

The action of such a discoloured lens described in the above paragraph would be to act to some extent as a yellow screen, which might be advantageous with a colour-sensitive plate, but with an ordinary plate it can have no beneficial effect. The use of coloured glass for lens work has been repeatedly suggested, more particularly, however, the use of violet or blue glass which, it was contended, would shorten the exposure, as has also the use of purpose-stained balsam, and this was patented in 1892 by Mr. Burchett. The disadvantage of these devices is, of course, that one must always use the screen, whether it is required or not. Many years ago Sir William Abney also suggested coating one of the lens surfaces with stained collodion for the same purpose, but the usual method of using separate screens is to be preferred.

The "Times" on Photographic Industries.

In the financial and commercial supplement of the "Times" of Monday last appears an appreciation of photography's place among the industries of the country. The organ of Printing House Square is chiefly retrospective but it sees in the diversity of materials which are employed in photography a safeguard from the evils which have overtaken other industries. In paying tribute to the superiority of British-made articles, it concludes, as to the photographic trade, that "its general sound and healthy state seems to justify a sanguine view of its immediate future." In tracing the development of photographic industrial undertakings, the "Times" is at the dilemma which every would-be statistician of photography finds himself in—a dilemma caused by the absence of figures. The Board of Trade returns photographic apparatus among other goods and classes materials with chemicals, so that isolated and unofficial figures—straws show how the wind of progress has become a chronic gas—are all there is to quote. Thus, for example, it is stated in indication of the great proportions assumed by the business of those who wait upon the amateur photographer, that Kodak, Ltd., develops on an average 8,000 negatives per day during the summer months, that the sales of Velox total more than £30,000 per annum, and that Messrs. Griffin dispose of 150,000 "cartridges" per annum.

Substantial Damages for a Broken Negative.

As reported in another column, a photographer has, in the Leeds County Court on Friday last, recovered £25 for a broken negative, shattered in transit on the railway. The matter is important to photographers, inasmuch as a County Court Judge has assessed the value of a negative at £25. None too much, no doubt, as it was the portrait of Lord Dudley, Lord Lieutenant of Ireland, and it was stated that the Dudley family had already given orders for some sixty guineas' worth of copies from it. In some former cases we have in our minds, which have come before the County Courts, judges have taken very different views of the value of negatives, assessing them at little beyond the cost of the plates and the chemicals and the packing case. In this instance the Judge took quite a different view of the matter. Photographers frequently have to forward by rail valuable negatives, which, often get broken in transit, and they have failed to recover from the company anything like their fair value.

Carriers' Responsibilities.

It may not be generally known that railway companies are protected by the Carriers Act, which limits the sum to be recovered in case of damage to £10. But if the sender, at the time of the booking of the parcel declares the value of it, and its contents, as being more than that sum, and pays the extra carriage upon it, the carriers become responsible for that amount in case of damage. Of course, the owner would have to prove in case of accident that the contents were of the actual value declared, and not a fictitious one. When the carrier, railway or other, accepts a parcel duly marked "fragile," and its contents are declared, it is assumed that he sees that it is properly packed for the journey, and if not he can refuse to accept it. But if it is accepted, he then takes the responsibility. When parcels are sent through the post the sum that can be claimed is limited to £2 unless the parcel is registered and fees paid according to the value. All parcels containing such things as negatives and the like should be marked "Fragile—With Care," the mere word "fragile" not being sufficient, according to the P.O. rules. When a parcel is received, whether by rail or post, and it is suspected that the contents have been damaged, it should be opened in the presence of the one who delivers it; or if, say, broken glass be heard when the parcel is shaken, the best way is to refuse acceptance altogether, when it will be returned to the sender, who will best settle the matter with the authorities. When a parcel is received by rail, the receiver should always satisfy himself that it has not sustained damage in transit before he signs for it, as signing for it implies that it is received in good condition, and there will then be a difficulty in recovering damages for injury.

* * *

Cloud Negatives: A Seasonable Hint.

The present is one of the best times during the whole year to obtain a stock of cloud negatives for printing into landscape pictures. During April, before and after a shower, there are usually very fine cloud effects. Many photographers may hold as a residue from last season a stock of plates that they would not care to trust to in the field; here, then, is an opportunity for turning them to a profitable account, instead of throwing them away. If the plates have become slightly deteriorated at the edges, or slightly impaired in other respects, it is of little moment for our present purpose; they will, except in extreme cases, answer very well for cloud negatives, a good stock of which will always be of service, and the more varied they are the better. In taking cloud negatives, a very common mistake is made in pointing the camera too much towards the zenith, so that when the negatives are obtained they do not, by reason of the lighting, harmonise with the landscape for which they are used. The case is, of course, different if the negatives are required only as cloud pictures to be used by themselves; but when they are to be used in conjunction with landscapes the camera should be directed more towards the horizon, so that the clouds occupy very much the same position on the plate as they would do if they were included in the landscape negative. The top of a house, or high building, is an admirable place from which to secure cloud negatives. Of course, the summit of a hill in the country would be still better.

* * *

Situations Vacant.

The disparity of numbers between the advertisements in our columns of operators and assistants requiring situations and photographers who have engagements to offer is to be seen at a glance,

and it might be supposed that professional photography is in such extreme straits that the business generally is unable to employ all those that it has educated. We are assured that, bad as times have been, and are, this is by no means the case. It may not be easy for an assistant, thoroughly well up to his work, to suit himself precisely as to locality, salary, and other matters; but there are plenty of vacancies at this, the commencement of the season, open to assistants thoroughly well up to their work. The assistants complain that masters want too much either in ability or terms of engagement. The masters, or those of them who are also masters of their business, complain principally that those who apply to them for situations are insufficiently equipped in knowledge for the posts they desire to occupy.

* * *

Assistants' Certificates.

The certificate scheme of the Professional Photographers' Association which was designed to obviate a well-recognised difficulty—that of presenting in the one case, and determining in the other, an applicant's capabilities at almost a glance, has not been received with the enthusiasm it deserves. We believe that although the applications for particulars have been many, applications for certificates have been comparatively few. The difficulty seems to be that the fees charged are considered too high. They are £2 for first grade, £1 for second grade, and 10s. for third grade. It seems, however, not to have been realised by most of those who apply for the particulars that the requirements of the examiners are such that any assistant who can pass the examinations is in a position to demand a salary sufficient to pay the charge without it being a tax. The idea seems to be that an operator who manages a small branch business, or who manages a medium-class ordinary provincial business in the absence of the principal, cannot in his own interests apply for less than a first-grade certificate, but that is an entirely erroneous idea. The first-grade certificate is intended to apply to men capable of such work as perhaps only a hundred or so studios turn out. The second-grade certificate would not be too easy to attain by those who, in the absence of means of comparison, consider themselves first-rate operators, and the third-grade would indicate a man who had received a thorough grounding in professional work. Men who have these capabilities, as a rule, receive reasonable remuneration for their services, and are capable of paying the fees; but, unfortunately, a very large proportion of those who ought to be skilled workmen, perhaps through no fault of their own, have never received the tuition or practice that would enable them to perform their work satisfactorily under any other circumstances than those they are accustomed to. The certificate scheme aims at discriminating between the skilled worker who can adapt himself to circumstances from his soundness of knowledge and the mere hanger-on to photography.

* * *

Employers and Assistants.

A point that seems not at present to be sufficiently valued by employers is the waste of time the certificate will avoid. Of personal character the certificate takes no cognisance: that will always have to be a matter of personal inquiry. But with regard to photographic matters, it will be evidence at the least that an independent body selected from the élite of the profession have satisfied themselves that the holder can substantiate his claim as far as it goes. While we are upon this point, we may refer to another in the same category. Many assistants do not realise the amount of trouble which an employer must take in making selection among a number of applicants. One incident which is often

brought before us as a grievance by assistants is that employers do not notify applicants of their non-success when a stamped and addressed envelope is supplied for that purpose. We would remind those who feel moved to speak in uncomplimentary terms of the conduct which they appear to accept as a personal affront that in many instances an individual reply to a number of applicants would tax a photographer with an amount of work incommensurate with the circumstances.

* * *

The Camera Club Company, Limited.

The report of the directors of the Camera Club for the year 1904 is not likely to be received by the shareholders with any special show of exuberance. The loss for the year amounts to £345 14s. 4d. The directors make the cryptic statement in extenuation that: "This is probably owing to the depression in trade," yet the members' subscriptions still total no less than £1,695 2s., and the receipts from provisions, wines, cigars, billiards, etc., amount to £1,612 6s. 10d. "There is something rotten in the State of Denmark." Can it be that a long course of lectures on everything under the sun but photography is having its effect on the well-being of London's Camera Club? Time was when the Journal of the Club recorded lectures that afforded a fund of pleasurable instruction to the members who worshipped at the shrine of Helios and paid their annual subscription; but now, alas! no special inducements are offered these praiseworthy individuals—who should constitute the backbone of the Club—beyond a late dinner, a comfortable arm-chair, and the use of the dark rooms and studio. The significant falling off in the amount of subscriptions recorded in the report tells its own tale.

DARK VIGNETTES.

A SHORT time ago we had something to say on the present status of the vignette, and on the circumstances in which the photographer can employ this form of photograph to advantage. Pursuing the subject, it may be well to refer to the type of vignette known as "Egyptian," in which the portrait melts into a dark surround. This style of graded print has had a great vogue in America, and if we wished to condemn it utterly we had only to draw attention to some atrocious effects which have been produced by this method. But there are signs of a revival of these black vignettes since the American vignetting devices have found their way on to our markets. Described briefly, they consist primarily of a card held in front of the lens which, being out of focus when photographed, merges into the body of the sitter, and thus forms a very delicately-graded vignette of any colour that the card selected happens to be. Of course, these cards usually match the grounds, thus a light grey card is used on a light grey background, a black into a black ground, and so on. The vignettters are further provided with methods of adjustment, mostly so that one can see the effect on the ground glass, but the mechanical devices merely differ in detail, and with them we have nothing to do.

The old method, which, however, suffered from the defect of not being easily adjustable and of only making a black grounding, was a cardboard mask that fitted in the bellows of the camera. Another way, though not very satisfactory, was to cover up part of the negative in the frame with cardboard, and to shade in the rest. Printing must be very deep—with most papers until bronzing results.

We think these vignettes are not subject to the same

restrictions as the more usual descriptions, and, though not liking them for the male sex, the same observations with regard to ladies' and children's costumes does not hold, though we think "dark vignettes" unsuitable for very young children. The background should match in tone the vignette card, as before mentioned; for a genuine Egyptian, the darker the ground the better, though it may be slightly graded on the shadow side, to relieve the face.

Very beautiful and striking effects are obtained by shading off a white dress, or the "drape," to black. Many Americans make very striking pictures in this way, but we think that the public will soon turn to the lighter and daintier type of portraiture, and disown the dark, though striking and artistic effects. Therefore, since it is the professional's duty not only to supply but to forestall demand, we draw attention to the matter.

SHORT VERSUS LONG WASHING.

At the period when albumen paper was practically the only one employed for prints it was thought necessary to give a very prolonged washing to ensure the removal of the last traces of hypo. It was very customary to leave the prints in water all night, and, in some instances, they were left soaking from the Saturday night till the Monday morning. This Journal, many years ago, was the first to point out that this long washing, or soaking, was detrimental to the quality of the prints, that it did not conduce to their permanency, but, on the contrary, it really impaired their permanency. We also showed that the quicker the hyposulphite and the hyposulphite of silver could be eliminated from the prints the better it was for their stability as well as for their brilliancy. Messrs. Haddon and Grundy, it will be remembered, produced analytical figures supporting the practice of short washing. They showed from experiments on Ilford printing-out paper that, after fixing, the whole of the silver is removed by thorough washing for ten minutes, and they pointed out that prolonged washing is prejudicial, as it dissolves out a part of the alum used in hardening the emulsion film.

Since then, during the last few years, a reaction seems to have set in, and short washing has become the order of the day. But it may be well to inquire if the conditions under which the short wash is often given are really sufficient to ensure the entire removal of the hypo salts? In the instructions issued with some of the gelatine papers a weaker fixing bath is given than that which used to be employed with albumen paper, while the time of immersion in it is also shorter; then follows, "wash for an hour." Now there is no question that the hypo can be as effectually removed in an hour, or even half that time, as it can be with many hours' soaking, if the work be properly done. But in many cases it is not; the prints are simply left soaking in a dish with the water changed four or five times during the time, and in the end they contain a certain proportion of hypo, with the result that after a time the prints show a change, and sometimes the cause is attributed to the gelatine paper. We alluded just now to the fact that stronger fixing baths, and longer immersion in them, were employed with albumen papers than are now used with gelatine, while it may be noted that the film is thinner and less absorbent in the former than it is in the latter. With the strong bath, and the long time in it, the conversion of the complex hypo salts of silver, insoluble in water, into the soluble salts was ensured in the print. But is this

always the case with weaker baths and shorter immersions often given with gelatine papers? Unless it is, no amount of washing will remove them, for they are practically insoluble in water. It is to the presence of these insoluble salts that the yellowing of so many gelatine prints may be attributed. The more completely a print is fixed, the more easily are the hypo salts removed from the paper, and the shorter washing it requires. As a matter of fact, as was proved years ago, the mere trace of hyposulphite

of soda, *pure and simple*, had very little injurious action on a print. It is the insoluble salts of silver that work the mischief.

These remarks, penned in the first instance with gelatino-chloride paper in mind, are still more applicable to collodion paper, the porous film of which renders the removal of the hyposulphite a more rapid operation. In this case also, of course, complete fixation is an equally important part of the process.

FLASHLIGHT POWDERS.

An extremely useful monograph has just appeared from the pen of M. Albert Londe,* from which we extract the following notes, prefacing the same by the remark that it deals with flashlight powders, which are obtainable commercially in France.

Several formulæ for making flash powders are given, and also the timely warning that, unless accustomed to chemical manipulations, the operator had better leave these severely alone, as they are extremely liable to explode—advice which we would also strongly impress upon our readers.

As regards the magnesium itself, it is pointed out that the finer the state of division the better it must be theoretically, but as in this state it naturally presents a greater surface to the air it is more liable to be oxidised. It should have a silvery grey metallic appearance, free from any signs of white which shows that it has oxidised more or less. It should also be quite free from lumps, which show the presence of damp.

Caution is given about keeping a stock of flash powders, and the dangers of sending by post or rail, and of attempting to powder the various ingredients. We would again add to this, and say that they should not be mixed by the operator at all.

Methods of Firing.

A flash powder to be satisfactory must fire at once, and this depends to some extent on the composition of the same and the method of firing. This may be by one match half buried in the powder and lit by a second; but there is danger of one getting burnt, unless the second match be held at the end of a stick or taper-holder. Special arrangements are obtainable commercially for safely firing by means of a match which is automatically struck at the desired moment.

Another method is by using a small piece of guncotton or pyroxyline, and lighting this by the aid of a match at the end of a cane. This is very satisfactory if the pyroxyline is pulled out into a loose line or tuft, and the powder sprinkled over it. There is another method in which the powder is tied up in a little bag of touch-paper, and fired by means of a tuft of guncotton. The most satisfactory is by firing it by means of electricity, and this is especially useful when two or more charges have to be simultaneously fired. A spark may be caused by a coil or a current may be passed through a thin platinum wire, which, rendered incandescent, is sufficient to fire the powder. It is, however, but rarely that these will be used by the average worker, because a convenient source of electricity is not always to hand.

Each method has, of course, its advantages and disadvantages, and personally our experience is that the guncotton and a long taper are the most satisfactory, even when two or more lots have to be simultaneously fired at different places, provided assistants can be obtained, and it is very easy to drill them into firing at a given signal, using the taper as a band-master's bâton.

Duration of the Flash.

According to M. Londe, it is somewhat generally assumed that the duration of a flash is very short, varying from 1-50th to 1-80th, or even 1-125th of a second. To prove the actual duration he used the well-known method of a revolving plate, and the light reflected from a mirror attached to one arm of a tuning-fork, the whole being electrically controlled, and on development the sinusoidal curve on the plate was measured and the duration of the flash calculated. Eleven powders were tested, one gramme of each being fired, and the longest exposure was found to be 1-5th of a second and the shortest 1-30th. We may as well call attention here to the fact that the totality of the flash has absolutely no relation to the efficiency of the same, but this will be referred to later.

The duration of the flash is dependent on various factors; but, calling the unknown ingredients of a flash-powder X, the following little table is instructive:—

		Duration of Flash.
1. X	100	0.07 sec.
Magnesium	150	0.07 sec.
2. X	100	0.10 sec.
Magnesium	175	0.10 sec.
3. X	100	0.11 sec.
Magnesium	225	0.11 sec.
4. X	100	much above 0.12 sec.
Magnesium	250	much above 0.12 sec.

Another instructive experiment was the firing of a freshly made powder and one that was old:—

	Duration.	Delay.
Fresh powder	0.03 sec. ...	None.
Old powder	0.15 sec. ...	0.06 sec.

The term "delay" means the interval between the application of the fire and the flash.

The weight of the charge must obviously play no mean part in the duration of the flash, and the following table shows it:—

	Duration.
1 gramme	0.03 sec.
2 grammes	0.05 sec.
3 grammes	0.07 sec.

The particular manner in which the charge is laid also plays a part; thus:—

	Duration.
1 gramme in a heap	0.2 sec.
1 gramme spread out	0.4 sec.

The method of firing affects the duration:—

	Duration.
Electric	0.14 sec.
Percussion cap	0.144 sec.
Match	0.188 sec.
Touch-paper	0.280 sec.

* "La Photographie à l'éclair Magnésique." Published by Panthiers-Villars, 65, Quai des Grands Augustus, Paris. Price 4 fr.

The plate affects the figures obtained, as shown, as follows:—

	Duration.
Lumière violet label (ultra-rapid)	0.12 sec.
Lumière blue label (extra-rapid)	0.10 sec.
Lumière yellow label (ordinary)	0.09 sec.
Lumière red label	0.05 sec.

Further researches are promised by M. Londe on this point.

The Closing of the Eyes of the Sitter.

It is a well-known fact that many flashlight portraits show unnatural effects about the eyes, and in many cases they appear half-closed, in some completely closed, and in others abnormally large, the last case being of course due to the absence of other lights in the room; but the following table by M. Londe proves how short a flash should be not to show partial or complete closing of the eyes:—

	Commencement of closing.	Finish of closing.
A powder	0.08	0.12
B powder	0.09	0.12
C powder	0.08	0.12
D powder	0.09	0.11
E powder	0.09	0.11
F powder	0.08	0.10
G powder	0.08	0.11

These results were obtained by the aid of the author's well-known chronophotographic camera, which practically consists of twelve lenses in three rows of four each, electrically opened for 1-200th of a second, with an interval of 1-100th of a second between each exposure. The ultimate result is that any powder that burns longer than about 1-12th of a second will not give a natural appearance to the eyes.

The form and nature of the flame and the "delay" and spluttering of the various powders are also of interest, and is specially instructive in the half-tone given; but it is useless to

give details without the illustration. Another table shows that some mixtures merely fuse, others explode, and yet again others fire silently. One of the most instructive illustrations is on the formation of the products of combustion. These may form such opaque clouds as to appear absolutely black to the plate, thus considerably reducing the actinic power of the light, and the author comes to the conclusion that all powders containing aluminium are particularly prone to the formation of these opaque clouds.

By the aid of his photochronograph the author studies the actinic power of the different powders, at every stage of the flash, and deduces the efficiency of the same. The first lens is opened at the moment of firing the flash, the second 1-100 sec. after the first, the third 2-100 sec. after the first, and so on, and the last 12-100 sec. after, so that the flash is thus analysed at different stages, and we extract the following table of the various actinic powers of one powder in increasing weights:—

Powder X.	No. of Lens.						
	1.	2.	3.	4.	5.	6.	7.
Figures measuring Relative Actinism.							
1 gramme ...	35000	30000	4000	—	—	—	—
3 grammes ...	80000	70000	35000	16000	4000	—	—
5 grammes ...	150000	135000	95000	48000	20000	10000	4000

Whilst these researches have all been made with commercial powders, the composition of which is unknown, they are certainly instructive, and point the way to similar researches with powders of known composition, which the author says he has not had the time to undertake, but that he may do so in the future. He has, however, done sufficient to prove, contrary to the statements of some, that a flash-powder made with aluminium is five times less actinic than one with magnesium.

ADVERTISING AND THE PROFESSIONAL PHOTOGRAPHER.

II.

LAST week I dealt on the newspaper advertisement as a signpost, and now I must particularise in cases which may be taken as representing the conditions commonly found in provincial towns. Bearing this in mind, let us see whether we can construct

Some Advertisements.

"A GOOD LIKENESS"

is the old-fashioned name
for a good portrait.

OUR PORTRAITS

are "good likenesses"—the
kind that your children's
children will treasure in the
years to come. The speci-
mens on show in our
window will convince you!

HYPO & PYRO,
16, High Street,
BLANKTOWN.

Two doors from G.P.O.

The "signpost" function is fulfilled—the information as to the proximity to the post office does that. The old-fashioned, indeed almost quaint, words of the heading attract attention, while the blank space serves as a relief to the mass of closely

printed matter of which the remainder of the page will probably consist, and thereby gives the advertisement greater prominence; and, finally, it has threefold weight, in that it not only appeals to possible sitters, but also to their children and grandchildren, who, if they do not already possess their relative's photograph, are thus more likely to remind them of it. Somewhat in the same style is

NEXT TUESDAY IS ST. VALENTINE'S DAY.

The old custom of sending
valentines has died out, but
we are sure that

A GOOD PORTRAIT

will always be received with
pleasure by your friends. We
have all the most fashionable
processes and the latest styles
in mounts.

Southtown cars pass our Studio.

PLATES & PAPERS,
London Road,
BROADVILLE.

The heading in this case attracts young people—the class to whom the fashionable processes and the latest mounts would most appeal, while the signpost function is again introduced. Early every week there is something which will serve as a leading; the idea is to make the advertisement read so that people recognise it as being that of the one studio, and yet not to be so familiar with it that they pass it without notice—which is what happens if the contents are not frequently changed. Not only the days of the calendar, but also local happenings can be turned to purpose. For example

ARE YOU INVITED TO THE MAYORAL BALL?

If so we shall be happy to be favoured with an appointment for a sitting to be given on your way to the Town Hall.

OUR STUDIOS

are fitted with a similar electric light to those in the studios in which the debutantes are photographed on their way to Their Majesties' Drawing Rooms. A letter making an appointment will have our immediate attention.

BLACK & WHITE,
The Square,
ROCKSANDS.

Perhaps not one of the sittings thus indicated will be given, but the chances are that very many people will be impressed by the fact that the advertisers are familiar with the modus operandi of the Court photographers, and when they do want to be photographed in evening or fancy costumes they will remember the advertisement. As for the three months before Christmas, every week should have a different advertisement, but all bearing on the season. Start with

THE MAILS FOR NEW ZEALAND

to reach there for Xmas will be made up at the end of this month, and those for Australia a week later. What better greeting can you send your friends "down under" than

A PORTRAIT OF YOURSELF,

and where can you have a better one taken than at the Studios of

A. CAMERA,
Chapel Street,
CHURCHTON?

Opposite Railway Station.

The unusual heading is certain to attract attention, and whether the reader has relatives abroad or not, his curiosity is aroused, only to be revived again later by

THE MOST ACCEPTABLE CHRISTMAS CARD

is one that bears the sender's photograph, especially if the latter be a good one.

THE SMITHJONES PORTRAITS

are known throughout the county for their excellence, and when mounted on any of the artistic Christmas Card mounts, a selection of which I am now showing in my windows, they constitute a Greeting which is treasured by the recipient long after the ordinary card is forgotten. There are only seven weeks to Christmas—so no time should be lost.

SMITHJONES STUDIO,
RIVERBROOK.

Then should follow the idea of giving enlargements as Christmas gifts, and, finally, two weeks before Christmas, the announcement that there is still time to have a sitting for the photographs to be delivered in time for Christmas. It would not call for very much time—not half as much time as is spent by some in grumbling at the bad state of trade—to draw up a different advertisement for every week in the year.

News Items.

A photographer should see that his name appears from time to time in the news columns of his local paper. For instance, in the mention of the photographing of a wedding party, the teams prior to a big football match, or the flashlight photograph at a dinner, it is very seldom that one sees the name of the photographer given. If there should be any happening of general interest, such as a railway collision or an explosion, of which the photographer has been fortunate enough to get some good negatives, it ought to be managed that the local newspaper's report of the occurrence should include some such notice as: "We understand that Mr. Hypo took some most interesting photographs of the effects, two of which appear in this week's 'Graphic.'" It is not much, it is true, but it serves to keep the name before the public, and, after all, there are some critics who are unkind enough to say that Miss Marie Corelli is the biggest advertiser of the day, and they are not referring to the advertising of her books which the publishers give her, either!

The Usual Thing.

Granted that this style of advertising is a departure from the "usual thing"; but when respect for the conventional is found to pay so badly that it is barely possible to make ends meet, let alone make any provision for the future, it is high time to depart from the beaten track, and as long as no breach of good taste is committed, there can be no valid objection raised. Anyway, it is ever so much better than the objectionable touting for free sittings which is unfortunately so prevalent in some districts. If anyone dislikes such advertisements, he does not feel it incumbent upon himself to write expressing his feelings; but we think that if the truth were known some very much more unpleasant replies have been received to the offers of free sittings than that of the clergyman recently reported in the "B.J.": "Is thy servant a hen that he should do this thing?"

What to Avoid.

It will be noticed that in not one of the suggested forms of advertisement is any mention made of prices, the reason being that we think it would lead to further price-cutting, of all the forms of competition in professional photography, the most objectionable. It is a game of "beggar-my-neighbour," for which the public is not in the least grateful. Photographs are not a necessity, and when people are buying luxuries they do not consider the question of prices as they do when necessities are required. Neither should there be any mention of one's competitors: even if one does not go as far as the unfortunate man who set up the sign: "Stop here, do not go elsewhere to be cheated," the impression created is likely to be other than one intends. People do not mind being told that one can do this, that, or the other, but they do resent one usurping their right to draw comparisons between the advertiser and his competitors. Yes, in advertising photographs it is decidedly good policy not to advertise how cheaply one can work; rather should arguments be advanced as to the wisdom of paying a moderate price for a high-class photograph.

Window Display.

A few photographers whose studios are on the upper floors of buildings in the main streets of our large towns, are limited to a small showcase at the door giving access to their stairway, but the great majority of photographers have, we take it, a shop, or other large window, available for the display of specimens. These windows afford opportunities for advertising which are only too frequently wasted by their proprietors, a fact which can be demonstrated by observing the number of passers-by who stop to examine the contents of the window as compared with those of the neighbouring businesses. This is not to be wondered at when one sees that the greater part of such displays consists almost entirely of closely packed cabinets, with here and there an enlargement, the subject of which is so unattractive as to lead one to think that for some reason the order is one which has been left on the photographer's hands, and rather than waste it he has put it in his window. This should not be so. If there be any one thing more than another that the public likes to-day, it is a picture, ample proof of which is afforded by the numerous weeklies and monthlies, the pages of which are more than half illustrations. This taste is one that should be

Gratified by the Photographer.

If his everyday orders are not such that they yield material of pictorial interest, he should look about him and he will soon find subjects which, if not of sufficient interest as to

make copies worth selling, will still cause passers-by to stop at his window. Despite Kipling's lament "the muddled east" still ranks high in the public estimation, and in nineteen towns out of twenty, a snapshot of the local club's first goal (with matches starting at 2.30 the light is frequently good enough for the exposure) in the Saturday afternoon's match, will give a bromide print, which, if shown on the same evening or the Monday morning will, to a very large number of people, make the window containing it the most attractive in the street. Is there a talk of town improvements? In the town hall or free library there are almost sure to be some engravings of the town in times past, and a request in the right quarters will generally bring the permission to photograph them. Thus with a view of the existing conditions, there is the material for two pictures, "The Past" and "The Present," and if the scheme be carried out, a photograph of the architect's plan will give a third, "The Future." There may be a flood or heavy snowfall: as quickly as possible have views of the town in its unusual aspect on show. In short, make the window of the town what the illustrated papers are to the country at large—a mirror of passing events. As a change, a part of the window may be turned into

A Picture Gallery.

at but a slight cost, by means of two or three of the Autotype Company's excellent reproductions in carbon of celebrated paintings, inexpensively framed in stained oak. In Essex and Suffolk towns the works of Constable and Gainsborough in Norfolk old Crome, in any of the cathedral cities Raphael and Botticelli may be indicated as especially suitable, while elsewhere the reproductions of any of the better-known paintings in the national collections will generally be found to prove of interest. Apropos of this subject, it may be mentioned that we do not see why these reproductions should not be sold by more photographers than are at present doing so; the same remark applies to photographs of celebrities, even in the bromide postcard form, now that it has so largely taken the place of the silver cabinets. The trade in both these lines is chiefly done by the stationers, but it seems to us to fit in more appropriately with the photographer's business. Whether there is much profit or not attached is beside the present question, but they would undoubtedly add to the attractiveness of the average photographer's window.

I must leave to the third and concluding article of this series some notes on other modes of advertising—viz., on railway stations, in local publications, and by post.

W. J. CASEY.

THE WEEK IN HISTORY.

A Step Forward in Collodion Emulsion.

THE correction of the fogging propensities of a collodion emulsion by addition of an acid has been the study of workers in that process so long that it is probably beyond the recollection of many exactly when it came into practice. It was one of the many valuable contributions to photographic technics which Carey Lea, of Philadelphia, published in *THE BRITISH JOURNAL OF PHOTOGRAPHY*, and appeared in the issue of April 1, 1870. The acid which Carey Lea recommended was aqua-regia in the proportion of about 1 to 2 drops per ounce of collodion. "The effect of the acidifying," he writes, "is very marked. The excess of nitrate of silver, which before could not be brought into actual solution without fogging, has no longer any such tendency. This I have tested critically

by dissolving the whole of the nitrate of silver beforehand, and then keeping the materials for a day, or even two days, in contact with frequent shaking. Even with this treatment, the negative comes out perfectly clear and bright, without the use of bromide in its development."

Big Emulsion Work.

It may be as well to mention here that at this time there was no washed emulsion. The plate was coated with the haloids in it; they were then washed out of the film after the collodion had set. Then an organifer was applied. Washed collodion-bromide emulsion process was not introduced until some four years later, when the late Mr. W. B. Bolton published it. At this time the worker had to make his own emulsion as well as coat his own plates with it. Still, the process was in much

favour with amateurs, some of whom were very enthusiastic. I remember seeing in the photographic section of the Victorian Exhibition (1897) at the Crystal Palace some three or four views in North Wales, taken direct in the field on plates of his own preparation, 24 in. by 18 in., by Mr. Osmond R. Green. They were prepared as above. Most who saw these pictures surmised they were enlargements, for there was no intimation in the catalogue that they were direct pictures. The lens used for these pictures, I am told, was a single landscape one of some seven inches in diameter, and nearly three feet focus. I imagine that there are few amateurs now who would care to take such an apparatus about with them, although they can get the plates ready prepared.

Niépce and Daguerre.

The overtures from Daguerre to the solitary Nicéphore Niépce were proceeding during the year 1827, and, as is seen from the correspondence between Niépce and his friend Lemaitre, the engraver, there was great reluctance on Niépce's part to share the knowledge he had so hardly acquired. His distrust of Daguerre peeps out in a letter to his friend, written almost exactly seventy-eight years ago. "I forgot to tell you," he writes on April 3, 1827, "in my last letter that M. Daguerre has written to me, sending me a little drawing in sepia, and finished by his process . . . but it is difficult to say how much is the result of the process only."

HISTORICUS.

CONTROL OF THE DEVELOPMENT FACTOR AT VARIOUS TEMPERATURES.

[A Paper read before the Royal Photographic Society.]

THE chief difficulty in the practice of photography has always been to decide how long to continue development in order to obtain such contrast between the different tones of the negative as shall give the desired result in the final print.

The old plan of judging by sight in front of the red lamp, though giving very good results in the hands of experienced men, was apt to fail in cases of unusual variation either in exposure or in the temperature, etc., of the developer, and is inadvisable when using the modern isochromatic plates.

"Development Factor," i.e., Contrast.

Hurter and Driffield were the first to assign an exact meaning and numerical value to the steepness of gradation between the different tones of a negative, which they expressed by the name of "Development Factor" and represented by the Greek letter gamma (γ) this being on their diagrams the tangent of the angle between the line of correct exposure and the base line representing the inertia of the plate. Hurter and Driffield determined it graphically on their charts, but it can also be calculated arithmetically by multiplying the mean regular highest differences of the successive densities measured in the photometer by the figures 3.3, and this arithmetical method we have found to be a very useful check on the accuracy of the graphical determination.

The values of γ which are used in this paper have been obtained by taking the mean between the graphic value and that obtained arithmetically.

The Subject and the Development Factor.

Hurter and Driffield also point out that while a development factor (γ) of 1.0 represents a negative true to nature it may be necessary, in order to obtain the desired quality of print, either to continue development for a longer time till a higher factor is reached, or so to shorten the period as to obtain a lower one. They suggest a $\gamma = 1.3$ for landscape, $\gamma = 1.0$ for interiors, and $\gamma = 0.8$ for portraits.

Development by Time of Appearance.

Later on, the researches of Watkins led to the well-known system of developing the plate for a certain multiple of the time of the first appearance of the image in order to obtain a definite development factor (γ), such multiple depending on the value, and in some cases the dilution of the developer, and it is only due to Mr. Watkins to say that his method when used according to his directions has within certain limits given excellent results and proved to be most valuable in photographic work.

One of the drawbacks inherent to the Watkins system is the difficulty of noting the exact time of first time appearance of the image, and unless the Watkins factor is a low one any error in estimating the time of appearance is so much magnified as to vitiate the result

obtained. Our own experiments showed us that considerable errors were easily made in determining the time of appearance, especially when using slow working developers, and it was not possible with certainty to develop so as to obtain the given γ that was desired. Moreover, though Mr. Watkins claims that his system compensates for variations of temperature in the developer within limits, we have found in practice that temperatures ranging from 15.5 deg. C. to 5 deg. C. do require an alteration in the Watkins factor.

The Effect of Temperature.

The later researches of Driffield and the valuable work of Mees and Sheppard have indicated the relation of the development factor (γ), to the time of development and suggest methods of control. We may mention that for some time after we commenced the experiments on which this paper is based we were unaware of the work which Messrs. Mees and Sheppard were doing in regard to development factors. They, however, as well as Driffield, work at a standard temperature, and have not as yet, so far as we know, published anything dealing directly with variations in the development factor (γ), due to the temperature of the developer.

Now in practical work it is very difficult to insure that the dark room, water supply, and developer, shall always be at the same standard temperature; and working at Arosa, Switzerland (6,000 ft. high), where the outside temperature often falls below -20 deg. C., we found it impossible.

We therefore made experiments with a view of determining how the development factor (γ) was affected by conjoint variations of time and temperature, in order to construct such a curve or table as would enable us, on a given plate and with a given developer, to obtain the desired development factor when working at any specified temperature between 7 deg. C. and 17 deg. C.

The Method of Working.

The plates were exposed in a modification of the Hurter and Driffield exposing machine, the wheel being so enclosed as to shield the plate from all light except that coming from the standard candle.

The exposed plates were then cut up into strips and washed in water for a definite time, so as to ensure the equal absorption of the developer; and different strips from the same plate were then developed for varying times in a considerable quantity of the same developer at the temperature selected; they were then without washing fixed in an acid fixing bath, washed, dried, and the densities measured in the photometer.

In order to maintain a constant temperature during the course of each experiment, a large water bath, cubical in shape, containing about twelve litres of water, was constructed, and inside this was a deep developing dish made of thin tin plate so placed that it was

at least 5 cm. from the walls of the water bath, and by means of projecting pieces of tin the dish could be kept in motion while immersed in the water bath and covered in from stray light. Provision was also made in the water bath for a vessel of thin glass to contain the mixed developer before use, and for the large wood-shielded thermometer which also acted as a stirrer.

Preliminary experiments with a delicate thermometer showed that the variation of temperature in the contents of the developing dish during the continuance of an experiment was generally so small as to be negligible, and in the most extreme case amounted to less than 0.5 C.

The developer used in all our experiments was the one which we found most suitable in our usual work, and contained in 1,000 parts, 4 parts of pyro, 40 parts of crystallised sodium carbonate, 20 parts of sodium sulphite, 0.5 parts of potassium bromide, and 1 part of potassium metabisulphite used as a preservative for the pyro solution.

We may mention that the presence of bromide in such quantity as we used has no influence on the development factor, it merely at a low factor lowers the speed of the plate, but it is useful in minimising the liability to fog during prolonged development, and so renders more easy the measurement of the densities in the photometer.

"Development Factor" and Development.

It has long been known that the development factor (γ) increases with the time of development, at first rapidly, and then more slowly as the plate nears its limit of development (γ_{∞}). This rise is usually more rapid in the case of a slow plate than in a fast one, as may be well seen in Fig 1, which shows diagrammatically the course of development of an Imperial fine grain slow plate and of an

Imperial flashlight plate, both developed at a temperature of 10.5 C. for the number of minutes shown on the base line of the diagram. The points marked \times being those directly observed, those marked \circ being calculated by the formula of Mees and Sheppard,* $\gamma_t = \gamma_{\infty} (1 - e^{-kt})$.

Temperature of developer within the range of our experiments, while having no influence on the inertia and speed of the plate, has a considerable effect on the development factor. In any given time

the higher the temperature of development, the higher the development factor (γ) obtained, the increase being fairly regular until the plate begins to near its limit of development, as will be seen from the observations recorded on Diagram Fig. 2.

Fig. 2.

The Application of Results in Practical Work.

It is evident that it is possible for any given plate and developer, so to adjust the time of development to the temperature of the developer as to obtain an equal development factor (γ) at various temperatures of development, and the following experiments and the calculations therefrom show how this may be done, using as an example "Kodoid" plates (batch No. 654), and the developer mentioned above.

Three plates, A, B, and C, were exposed in the H. and D. exposing machine to a maximum exposure of 80 C.M.S.

Plate A was cut into four strips, A₁, A₂, A₃ and A₄, and these were developed at a temperature of 17.5 deg. C. for 3, 5, 7, and 9 minutes respectively, the densities measured in the photometer and the development factor (γ) obtained in each case was:—

A ₁	A ₂	A ₃	A ₄
$\gamma = 0.95$	1.16	1.48	1.7

Plate B was similarly treated, except that in this case the development took place at 12.3 deg. C., and development factors obtained were:—

B ₁	B ₂	B ₃	B ₄
$\gamma = 0.815$	1.00	1.265	1.515

Plate C was cut into five strips, which were developed at 7 deg. C. for 5, 6, 7, 8, and 9 minutes respectively. The development factors obtained were:—

C ₁	C ₂	C ₃	C ₄	C ₅
$\gamma = 0.845$	0.95	1.035	1.125	1.22

The results obtained in these experiments are shown together in the following table:—

DEVELOPMENT FACTORS OF "KODOID'S."

Developed for		Minutes.						
		3	4	5	6	7	8	9
at	17.5 deg. C.	0.95	—	1.10	—	1.48	—	1.7
	12.3 deg. C.	0.815	—	1.00	—	1.266	—	1.515
	7.0 deg. C.	—	—	0.845	0.98	1.035	1.125	1.22

* "Photo Journal," July, 1903; November, 1904.

They were then plotted on squared paper, the development factors as ordinates, against the temperatures as abscissæ, as in Diagram Fig. 2.

A Chart of Development Times for Given "Factors."

On joining by an even curve the points representing similar times, a series of time lines is obtained, and as the increase is due to increase of time, and, within the limits of our experiments, appears to be regular, the intermediate time points for 4, 6, and 8 minutes are marked on the vertical lines representing temperatures of 12.3 deg. C. and 17.5 deg. C. midway between the lines already drawn. These points, together with the corresponding ones on the line of 7 deg. C., are also connected by even curves.

This being done, the times necessary at each degree to produce a development factor γ of 1.3 may be measured off. The squares shown in the diagram were in the original diagram further divided

into ten, horizontally and vertically, and correct measurement was rendered more easy. Thus, for example, on the line of 10 deg. C. the time lines which cut the horizontal representing $\gamma = 1.3$ are 12.25 divisions of the squared paper apart, and the $\gamma = 1.3$ line is 2.25 divisions above the 8-minutes line then

$$\frac{2.25}{12.25} \times 60 = 11$$

is the number of seconds to be added to the 8 minutes represented by the lower line in order to arrive at the time of development at 10 deg. C. necessary to produce a development factor of 1.3; that is 8 minutes 11 seconds.

In this way the following numbers have been obtained at

	min.	sec.		min.	sec.
7 deg. C. ...	9	50	13 deg. C. ...	7	4
8 deg. C. ...	9	12	14 deg. C. ...	6	44
9 deg. C. ...	8	39	15 deg. C. ...	6	29
10 deg. C. ...	8	11	16 deg. C. ...	6	14
11 deg. C. ...	7	47	17 deg. C. ...	6	0
12 deg. C. ...	7	25			

For the purpose of detecting and eliminating errors of experiment, these times were then plotted on squared paper as abscissæ against the temperatures as ordinates, and a curve drawn evenly between the points as in Fig. 3.

It will be seen that in this case the points lie on a fairly regular curve, showing the absence of any considerable errors of experiment.

From such a curve the time of development at any temperature between 7 deg. C. and 17 deg. C. necessary to produce a development factor of 1.3 may be read off; and it is evident that in a similar manner curves suitable for other development factors may easily be calculated.

In Landscape Work.

Several films of the same batch were exposed on difficult landscape subjects of great range of tones, comprising snow-fields, buildings, and dark masses of fir trees. The temperature of the dark room having been ascertained, a supply of water was raised to the same temperature, and with this the film was washed and the developer compounded, the stock solutions being already at the temperature of the room in which they were kept. In this way the films, the dishes, and the developer were all at the same temperature, i.e., the temperature of the dark room and there was no variation of temperature during development.

On many occasions they were developed at various temperatures for the times indicated by the chart, and the results produced proved far superior to those developed by us on any other plan.

It has been suggested to us that the constants of plates, and more especially of films, alter so rapidly from time to time as to render such a system as we propose uncertain, but we found in practice that after an interval of six months, during which no photography was done it was possible to take up work again with the same batch of films and developing according to our table to get results of the same quality as before, showing that the constants of these films do not alter sufficiently within six months to materially affect the results. It is our hope that the makers of plates and films may be induced to issue with each batch of emulsion a table drawn up on the lines we have indicated for use with the particular developer they recommend, so as to enable photographers to develop with certainty at any temperature to a factor of 0.8, 1.0, or 1.3, as they may desire.

The slight expense involved in the preparation and issue of such a table would probably be more than compensated by the increased sale of plates accompanied by so sure a guide to their development.

W. B. FERGUSON, K.C., M.A., F.R.P.S.
B. F. HOWARD, A.M.I.E.E., F.R.P.S.

Tax on Photographs.—A correspondent to "The Express" writes that tourists at Pompeii, Naples, San Martino, and other Italian cities are practically prohibited from taking snapshots of historic places. Formerly a permit could be obtained for a nominal fee, but now the objects intended to be photographed have to be specified in writing, and a tax, varying from 5d. to 4s., is imposed for every negative.

THE Amateur Photographic Association of Victoria opened its annual exhibition on February 20 last in the Victorian Artists' Society's Galleries, Melbourne, and the catalogue and award list, kindly sent us by Mr. A. L. Henderson, who is touring in the Antipodes, show that our Australian cousins are as well to the front in the organisation and production of a successful exhibition as any society in the Old Country. The association is the oldest photographic society in Australasia, being founded in 1883, and boasts not only an extensive membership, but many first-class workers in its ranks. The catalogue of the exhibition is illustrated with many full-page half-tone reproductions of the pictures, and is a noteworthy production. In addition to the competitive classes, which appear to have been confined to exhibitors south of the equator, the loan collection of the Royal Photographic Society of Great Britain, to which the association is affiliated, formed an interesting display.

Photo-Mechanical Notes.

An Improved Glass-Cleaning Holder.

Most wet-plate operators are familiar with the vice used for holding the glass plate, when cleaning for wet-plate photography.

The form usually employed is shown in Fig. 1. There are, however, some objections to this style, viz., the projecting piece Z is not required, and is decidedly inconvenient; also, the plate when rubbed with a circular motion slips from one side to the other, unless very firmly clamped.

The writer has devised a holder, that has been in constant use for the last six months, which does away with these objections. Pressure from the thumb takes the place of the screw, and the plate is immediately clamped by one movement. The slanting piece, H, Fig. 2, securely locks the plate in the corner of the frame, thus preventing any movement of the glass.

One of these holders can easily be constructed from material generally found in a process workshop. The base-board A, Fig. 2, is made from some half inch wood, cut to the required size. Two strips of mounting wood, the length of the base-board and two and a-half inches wide, form the sides B C, Fig. 2.

These strips should have a couple of grooves routed or ploughed in one side of each (see section, Fig. 3, B C). Another piece of wood, three inches wide, is now required of the same thickness as the sides. When the necessary length is found, cut a tongue at each end to fit in the grooves described Fig. 3, i j.

Section of Holder, Showing Sliding Bar and Grooves.

Screw the side rails B C to the base-board A, parallel to each other. Cut another length of wood, two and a-half inches wide, D, to fit between B C at the top. Slide E (which should work easily) into its place. Make the rebate, that is to hold the glass, from some hard wood about one-eighth of an inch in thickness and one inch wide. Screw one of these pieces across the top of frame, Fig. 2, F (shaded portion), another length down the side G, the remaining piece cut one and a-half inches wide slanting down one side to one inch or less; screw into position as shown at H. The inside edges of rebate should be smoothed and slightly rounded.

The old form of holder can be altered without difficulty in the following manner:—Saw off X, Fig. 1. Take away the rebate

Y, and substitute a thin piece of wood shaped as previously described (see Fig. 2, H). The dotted lines in each diagram show the glass in position for cleaning. It is necessary to screw the holder down to the cleaning bench. W. J. SMITH.

THE OPTICAL CONVENTION.

In regard to this Convention, to be held, as we have already announced, at the Northampton Institute, Clerkenwell, E.C., from May 31 to June 3, we learn from the hon. secretary that offers to read papers should be sent to the Secretary of the Papers Sub-committee, Mr. S. D. Chalmers, Northampton Institute, E.C., who will be glad to submit them to the committee. During the Convention, an exhibition of optical and scientific instruments and appliances will be held in the great hall of the Northampton Institute. A large number of persons and firms have promised to send exhibits, among whom are Messrs. Ross, Ltd., Messrs. R. and J. Beck, Messrs. J. H. Dallmeyer, Ltd., Messrs. Newman and Guardia, Messrs. Aldis Bros., Messrs. W. Watson and Sons, and Messrs. B. J. Hall and Co.

In connection with the exhibition an illustrated catalogue of some 300 pages will be issued, which should make a most useful work of reference, and will, it is hoped, give very full information with regard to the British industries. The preparation of this is in the hands of an Exhibition and Catalogue Sub-committee, with Dr. Walmsley, Principal of the Northampton Institute as chairman. It is hoped that all those interested will apply for membership of the Convention, the subscription for which will be 6s. The hon. secretary, Mr. F. J. Selby, Elm Lodge, Teddington, will be glad to receive the names of those wishing to join the Convention. A guarantee fund has been opened, and the total of guarantees and contributions now amount to over £700. Promises of guarantees or donations should be sent to the hon. treasurer, Mr. E. B. Knobel, P.R.A.S., 32, Tavistock Square, W.C.

The programme of arrangements for the Convention is now beginning to assume a definite shape. The following reach us as we go to press:—

The Convention will be formally opened with an address from the President, Dr. R. T. Glazebrook, M.A., F.R.S., Director of the National Physical Laboratory, on the evening of Tuesday, May 30, and the gathering will extend over the four following days up to and including Saturday, June 3. The mornings will be devoted to papers and discussions, and in view of the interesting series of papers already announced, there is no doubt that this most important section of the proceedings will result in valuable contributions to optical science, and will fulfil the aims which those who have been active in promoting the Convention have set before them. In addition to the papers, demonstrations of apparatus of special interest will be given in the afternoons in the laboratories of the Department of Technical Optics of the Northampton Institute.

The exhibition of optical and scientific instruments will be held in the large hall of the Northampton Institute, and will be open daily to the public from 12 to 10 p.m., between May 31 and June 3 inclusive. The charge for admission will be 1s. during the day, and 6d. after 7 p.m.

The catalogue is now in active preparation. The arrangement made by the Exhibition and Catalogue Sub-committee that each section should be dealt with by an expert in the construction of the instruments represented in the section, together with an independent scientific member of the committee, will ensure that all classes of instruments shall be adequately dealt with and described. It is proposed to fix the sale price of the catalogue, which will be a volume of some 300 quarto pages, at 1s. 6d., while in large numbers of 100 and upwards the catalogues will be issued to firms at a cost of 1s.

each. The hon. secretary would be glad to hear at once from firms wishing to take a number of the catalogues for private distribution.

Arrangements for promoting the social interest of the gathering and for providing for the comfort and convenience of members attending from outside London, are now being considered by a Hospitality and Entertainments Sub-committee. In addition to the presidential address to be given on the Tuesday evening, which has already been mentioned, there will be an evening lecture by Professor Silvanus P. Thompson, D.Sc., F.R.S., on "The Polarisation of Light by Nicol Prisms and their Modern Varieties." On the third evening it is proposed to hold a conversazione, and for the Saturday afternoon a visit to the National Physical Laboratory at Teddington is proposed at the kind invitation of Dr. Glazebrook, the President of the Convention. Further particulars will be announced later, when the programme is more definitely settled. It will greatly help towards ensuring the social success of the Convention if intending members will send in their application at once. The subscription for membership is 5s. The hon. secretary, Mr. F. J. Selby, Elm Lodge, Teddington, Middlesex, will be glad to hear from those wishing to join the Convention.

The Local Societies' and Representatives' Sub-committee is dealing with the question of facilities for the attendance of visitors from a distance. The secretary of this committee is Mr. W. Rosenhain, B.A., 443, Gillott Road, Edgbaston, Birmingham. Mr. Rosenhain will be glad to give information in answer to inquiries, and will also be ready to receive applications for membership of the Convention.

Exhibitions.

PAISLEY.

LAST week the members of the Photographic Section of the Paisley Philosophical Institute opened their nineteenth annual exhibition in the Observatory Hall. The classes were not this year entirely restricted to members, one class being open to Associates of the Scottish Photographic Federation, and it received over fifty entries. The judges were Messrs. J. Craig Annan, William Goodwin, and Thomas W. Robertson.

The following is the list of awards:—

"Federation" Class.—Gold medal.—"A Picture Book," J. C. Robertson, Brechin. Silver medals.—"Of Highland Descent," A. Chapel Milne, Brechin; "A Foster Mother," Dr. Andrew Richmond, Paisley.

Members' Classes (Any size, any subject).—1, "Sweet Thoughtfulness," Sydney Crookes; 2, "Softly Falls the Silvery Light," R. W. Steel.

Instantaneous Class.—1, "In the City Garden," George Coghill; 2, "Harvesting," R. W. Steel.

Unframed Pictures.—1, "Woodland Study," Thomas Carlile; 2, "By Lone Loch Awe," George Murray.

Novice Class.—1, "Just Out," James Taylor; 2, "Figure Study," Hugh F. Hamilton; 3, "Beneath the Woods and Rocks Oftentimes for a Home," George Coghill.

Lantern Slides (Novice).—1, James A. Taylor; 2, James Lambie.

Lantern Slides.—1, R. W. Steel; 2, Thomas Carlile.

The exhibition remains open until April 8.

THE NORTHERN PHOTOGRAPHIC EXHIBITION.

THE Northern Photographic Exhibition will be held this year at the Leeds City Art Gallery from July 4 to August 12 next.

The judges will be Messrs. Reginald Craigie, Douglas English, B.A., F.R.P.S., Gilbert Foster, A. Horsley Hinton, and W. Edwin Tindall, R.B.A. Fifteen awards in the form of decorative bronze plaques, about 14 in. by 9 in., specially designed, will be at

the disposal of the judges in the following sections:—A.—Pictorial Photographs.—Eight plaques. B.—Scientific and Technical Photographs.—Two plaques. C.—Pictorial Lantern Slides (set of four).—Two plaques. D.—Scientific and Technical Lantern Slides (set of four).—One plaque. E.—Tri-Colour Lantern Slides (set of four).—One plaque. F.—Trade Exhibits (for the most attractive display).—One plaque. The adjudication of the trade exhibits will be by the ballot of the Executive Council and Exhibition Representatives combined.

The St. Louis collection of British Pictorial Photography, direct from the St. Louis Exhibition, will be one of the features of the show, while, with regard to the attendance of the public, it has been decided to add interest to the exhibition by awarding a picture value one guinea to the person whose visit registers 1,000 at the turnstile, and likewise for each succeeding 1,000th visitor. The picture to be selected by the winner from the walls of the exhibition. Scholars attending any of the public schools will have the privilege of attending the exhibition at a nominal admission of a penny each in parties of twelve or more. Lantern lectures on popular and photographic lines, and also chamber concerts, will be among the attractions. All exhibits (excepting lantern slides) must be delivered not later than Tuesday, June 20, 1905, addressed to F. G. Issott, Hon. Secretary, Northern Photographic Exhibition, City Art Gallery, Leeds. Lantern slides must be sent addressed to F. G. Issott, 62, Compton Road, Harehills, Leeds, who will furnish entry forms and full particulars on application.

[Owing to pressure of space the list of Forthcoming Exhibitions and Competitions is unavoidably left over this week.]

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents were made between March 13 and 18, 1905:—

PLATE HOLDERS.—No. 5,198. "Improvements in photographic plate holders and the like." Walter Taylor, 20, Champion Park, Denmark Hill, London.

PLATE WASHER.—No. 5,430. "Photographic plate washer." Hector Ross Urquhart, 134, Florence Road, Wimbledon, Surrey.

PHOTO-LITHOGRAPHY.—No. 5,473. "Improvements in the production by photography of lithographic or other printing surfaces." Sir Joseph Causton and Sons, Ltd., and William George Meredith, 24, Southampton Buildings, Chancery Lane, London.

CINEMATOGRAPH MACHINES.—No. 5,676. "Improvements in and relating to cinematograph machines." Frederick William Butcher, 322, High Holborn.

CINEMATOGRAPH MACHINES.—No. 5,682. "Improvements in cinematograph projecting machines." Charles Urban, 48, Rupert Street, London.

NEGATIVE PLATES.—No. 5,780. "Improvements in and relating to negative plates for photographic printing." William Jay Little, 7, Southampton Buildings, Chancery Lane, London. (Date applied for under Patents Act, 1901, March 19, 1904, being date of application in United States.)

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

CELLULOID.—No. 5,280, 1904. "It is claimed that celluloid may be prepared without camphor by dissolving the pyroxyline in turpentine, certain ketones, etc., with methyl alcohol and ether." R. E. M. Ortmann, 37, Park Road, Forest Hill, London.

THREE-COLOUR PROJECTION.—No. 7,179, 1904. "Protection is claimed for a system of projecting the three positive colour records in which a set of mirrors are arranged outside the lens. The system of mirrors may consist of four single mirrors, in which case the central colour record is projected directly to the screen, or the two central mirrors may have reflecting surfaces on each side. The arrangement is suggested for cinematograph projection, and it is claimed that under favourable conditions the mirrors can be used for producing the original negatives as well as for projecting the resulting colour records on the screen. In any event means are provided not only for adjusting the angles of the reflectors as already mentioned, but also for varying their distances from one another and from the lens. The mirrors should be enclosed in a box with a suitable opening or with suitable openings, to allow the image or images to pass to the lens, and the box of mirrors may be so small as to be easily attached to the lens hood." W. N. Lascelles Davidson, 20, Middle Street, Brighton.

PRINTING BORDERS.—No. 9,515, 1904. "The patentee prepares, from glass, celluloid, or paper, (1) a border-negative and picture-mask, (2) a border-mask and picture-opening. The first consists of a marginal negative design through which the border is printed, and a central opaque portion to protect the paper from light. The second enables the border to be masked whilst the print is taken through the opening, which was opaque in the 'border-negative and picture-mask.' These two parts, 1 and 2, are joined together in register to form a kind of envelope. The sensitive photographic printing paper is placed in this envelope and held fixed in relation to the two sides while the border is printed from one side of the sensitive paper, preferably through the unsensitised side and the picture from the opposite side, either simultaneously or one after the other; or both picture and border may be printed in succession from the same side of the sensitive paper by reversing the latter so that the sensitive side comes in contact first with one side of the envelope or folder and then with the other side." P. A. Hillhouse, Whitworth, Bushby, Scotland.

TONING BROMIDES.—No. 10,898, 1904. "The claim is for a method of toning silver pictures by treating the picture first with a solution of a manganic salt, a ferricyanide and an acid, and then with an alkaline solution of a ferricyanide, and afterwards colouring in any suitable manner the manganese picture thus produced. The following is a specimen of the way the process is carried out:—Solutions: A.—3 c.c. of 10 per cent. potassium bromide solution, 2 c.c. of 10 per cent. citric acid solution, 3 c.c. of the manganic solution prescribed below. B.—20 c.c. of 2 per cent. potassium ferricyanide solution, 80 c.c. of water. The manganic solution to be added in solution A. is made from 150 grams of sodium tartrate, 25 grams of crystallised manganous sulphate, 100 c.c. of normal caustic soda solution, 100 c.c. of 4 per cent. potassium permanganate solution. Bromide prints are treated in a bath composed of equal parts of A. and B. until the silver has disappeared. It is washed for a short time and then brought into Bath II., whereupon it assumes a brown colour. Bath II.—90 c.c. of 2 per cent. potassium ferricyanide solution, 10 c.c. of normal caustic soda solution. The manganese picture thus produced is now again washed and may be coloured in the known manner by means of aniline hydrochloride, for instance." A. G. Bloxham, Birkbeck Bank Chambers, Southampton Buildings, London, for the Neue Photographische Gesellschaft, 27, Siemensstrasse, Steglitz, Berlin.

PRINTING FRAMES.—22,960, 1904. "1. A printing apparatus consisting of a curved wooden frame, carrying a curved piece of glass, a cover cloth fixed to one end of the frame, a roller mounted

on the opposite end of the frame adapted to receive the free end of the cover cloth in such a manner that the strain exerted on the cover cloth by the roller acts tangentially to the curved piece of glass." F. Nusch, 81, High Holborn, W.C., for the Brothers Pabst, 51, Ludwigsstrasse, Ludwigshafen, Germany.

VIEWING PHOTOGRAPHS SUCCESSIVELY.—No. 22,999, 1904. "Protection is claimed for an arrangement whereby a pile of photographs or transparencies, each member of which is placed horizontally, is brought one by one into a vertical position, i.e., at right angles to the axis of the lens. The pictures are disengaged one by one by a series of hooks and notches, and the method is shown as applied to a stereoscope." Charles Fougerat, 149, Avenue de Saxe, Lyons.

CAMERAS AND DARK SLIDES.—No. 27,909, 1904. "This invention relates to an improvement in cameras and plate-holders which has for its object to quickly and perfectly close the slot through which the light-shield slide of the camera or of the plate-holder is introduced and thus avoid any possibility of injury to the photographic plates or films by reason of light entering the camera or plate-holder through the slot." J. S. Wright, Duxbury, Plymouth, Mass., U.S.A.

"BARNET" Showcards.—Messrs. Elliott and Sons look after their advertising literature in no parsimonious fashion. Their policy in this direction is shown in their use of designs by well-known artists, but perhaps the dealer who reads these lines has most need to note the very ornate and attractive window and show cards now being issued to draw the notice of the customer to the many Barnet products. We are advising our dealer friend for his good when we urge him to obtain the parcel of cards which Messrs. Elliott will send on application.

SCIENCE Hot from the Press!—The "Globe" of last Friday announces that "MM. Gullstrand and Von Rohr have invented an achromatic lens known as the 'verant,' which is made by the well-known firm of Carl Zeiss, and gives the stereoscopic or 'solid' effect to an ordinary single photograph."

A NEW LIST.—The Teila Camera Company, of 110, Shaftesbury Avenue, London, W., send us their latest catalogue of up-to-date photographic apparatus, lenses, and sundries. The company has made it their business to supply every make of apparatus at lowest cash prices, or on a system of weekly or monthly payments. They also give advice on apparatus, either personally or by post, and have for a number of years made a specialty of exchanging old cameras for new, or making an allowance on old ones in part payment for new. A large stock of second-hand apparatus is on hand, and they are prepared to lend on hire any class of camera or apparatus appearing in their second-hand list. Special terms are quoted to professional photographers, and the present list, which is very complete and well illustrated, contains practically everything likely to be required by the amateur or professional. It will be sent post free on application.

THE handsome list of microscopes and accessories made by the Bausch and Lomb Optical Co., reaches us from the British agents, Messrs. A. E. Staley and Co., 19, Thavies Inn, Holborn Circus, London, E.C., who will send it to applicants on receipt of three-pence for postage.

ART Fails to Draw.—The report of the National Gallery for 1904, just issued as a Parliamentary paper, is the last of the series by Sir Edward J. Poynter, as his second term of directorship was prolonged only to December 31. The gallery does not seem to be holding its former position in popularity. The attendances have been declining both on free days and Sundays, and also on students' days. The attendance also at the Tate Gallery last year was 187,899, against 206,494 in 1903.

New Apparatus, &c.

"Special Ruby" Camera Outfit. Made by the Thornton-Pickard Manufacturing Company, Limited, Altrincham.

The Thornton-Pickard Company have placed upon the market a special form of their well-known "Ruby" camera at a price which secures a high-class instrument within the buying powers of those of moderate purse. £5 5s. will purchase the complete set in the half-size—camera, shutter, tripod, and lens—and, with due regard to the thorough and substantial manner in which the apparatus is made out, the price is one to which the Thornton-Pickard Company legitimately point as indicating an achievement in the production of reliable photographic cameras. Turning to the technical points of the outfit, the camera extends to 16 inches between lens, panel, and plate, and though built in the conical pattern, the front is 4½

inches in width, a dimension which permits of stereoscopic working done with a pair of lenses, but does not overtax the maker's powers in producing an instrument which folds to the slimmest proportions. There is great rise of front, sufficient to bring the lens on a level with the top of the plate. Although essentially a stand camera, the instrument can conveniently be fitted with a focussing scale for use in the hand, and the back racks close to the front for use with lenses of short focus. The tripod is attached by rotating turntable, which is firmly held in place, and is released by a set screw. A Beck rapid symmetrical lens, with diaphragm, completes the outfit, which, as we have said, costs £5 5s. with one double dark slide, and should certainly gratify prospective purchaser, as it has ourselves, after a careful inspection. A circular, descriptive of the apparatus, is issued by the Thornton-Pickard Company, and gives the prices for the other sizes from ½ plate to 18 by 24—in which the camera is made.

The price list of the Camera Construction Company, Eagle Works, 10, Ham Grove, Hackney, London, N.E., runs to more than twenty pages, but is worth possession by dealer, professional, or amateur photographer, since every article is actually manufactured by the company. The company's specialties include field and studio cameras, printing frames, and other accessories for photography and photo-etching.

A new pattern of Kodak is announced by the Kodak Company, and one which dealers may well have ready for early introduction to

their customers. The newcomer will permit of each picture being focussed on the ground glass without disturbing the roll of film. It will be made in 5 by 4 size, and will carry plates as well as roll films.

THE agency of the Smith Multifilm Plate, recently mentioned in this column, has been undertaken by Messrs. A. W. Penrose and Co., 109, Farringdon Road, London, E.C.

Commercial & Legal Intelligence

FALSE Pretences.—At the Birmingham Police Court last week, Oswald Arthur Fleming, photographer, was charged on remand with obtaining four packets of cabinet Velox papers and other articles, from Messrs. Needham, Ltd., Old Square, by false pretences. According to the evidence, the prisoner went to the shop of Messrs. Needham, and on the representation that he was in the employ of Mr. Charles Worcester, fine art publisher, of Bristol, he obtained the goods on credit. It transpired, however, that he was not employed at that time by Mr. Worcester, but some time previously he had been engaged as his traveller. He was sentenced to 14 days' imprisonment.

BANKRUPTCY.—At the Leeds County Court on Monday, before Mr. Registrar Marshall, William Elland, photographer, of 14, New Briggate, Leeds, and residing at 81, Hill Top Mount, Leeds, appeared for his public examination. The liabilities amounted to £536 2s. 4d., and the assets to £178 7s. The alleged causes of failure were "bad trade and three bad seasons." For twelve years the debtor was manager for a wholesale photographic dealer at Manchester, and afterwards became secretary and manager for Eddison and Co., Ltd., Leeds, in which he invested £500. In July, 1897, he purchased the branch business at New Briggate for £600, and he was obliged to spend a further £150 in new stock and apparatus. The examination was adjourned.

TWENTY-FIVE Pounds for a Damaged Negative.—At the Leeds County Court on Friday last an action was brought by Alexander Good, photographer, of 25, Camp Road, Leeds, against the Midland Railway to recover £100, the value of the negative of a photograph of Lord Dudley, Lord-Lieutenant of Ireland, which the plaintiff alleged was broken while in transit from Leeds to Messrs. Morgan and Kidd, of Richmond, Surrey, on October 7 last. The negative had been a source of considerable income to the plaintiff. In consequence of its breakage he had been unable to execute an order amounting to £156 10s. Judgment was given for the plaintiff, the Judge finding the value of the negative to be £25.

ANOTHER Copyright Case.—A copyright case of considerable interest and importance to photographers generally was decided last week at the Bangor County Court. Penalties under the Fine Arts Copyright Act, 1862, were claimed by Miss Charlotte Daw from Mr. John Wickens, photographer, of Bangor, for, as alleged, fraudulently affixing his name to two water-colour paintings executed by her, and afterwards selling them to the late Marquis of Anglesey. Miss Cox is a professional painter. In April, 1903, defendant asked her to execute two water-colour paintings of the theatre at Anglesey Castle. The paintings were finished, and handed over to Mr. Wickens, and subsequently plaintiff saw the two paintings among the effects to be sold at Anglesey Castle. She found they bore Mr. Wickens's name, which, in effect, announced to the world that he was the author of those paintings, which was not only a fraud upon her but upon the public. The pictures were bought by a dealer, from whom defendant afterwards bought them, and displayed them in his window. Defendant

repudiated any liability, alleging the pictures were produced under his direction, and issued from his studio, after he had "finished" them. Replying to her counsel, the plaintiff said defendant had paid her £12 for this and other work done by her for him. Other evidence having been given the Judge said that, in his opinion, the Act did not apply, and that if he were asked he would say he did not think Mr. Wickens had acted fraudulently. As far as he could see, plaintiff had sustained no damages at all, and he had no doubt the result of the action would be to enhance her business a great deal. The jury took fully an hour to consider their verdict, and, on returning to court, said that on the first count they found there was no fraudulent intent; and, on the second, that the plaintiff imposed no restrictions on the defendant. As to the third point, they thought it was not right of Mr. Wickens to place his name on Miss Cox's work. His Honour said the onus of proving a contract rested on the plaintiff. The verdict and judgment was, therefore, for the defendant, with costs.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

March.	Name of Society.	Subject.
31	Greenock Camera Club	"Photography" and "A. P." Prize Slides.
31	Wakefield Photo. Society	<i>Enlarged Negatives.</i> Demonstrated.
31	Aberdeen Photo. Assn.	Mr. F. Rust.
31	Watford Photo. Society	Instruction Night.
31	Watford Camera Club	Printing Methods—Gum Bichromate.
31	West London Photo. Society	Mr. J. O. Grant.
31	Watford Camera Club	Lecture by Mr. C. O. Murray.
31	Watford Camera Club	Photographic Lecture by Mr. W. D. Welford, F.R.P.S.
April.	South London Photo. Society	Annual General Meeting.
3	Camera Club	<i>A Journey to South America.</i> Mr. F. Mearns-Duncan.
3	Southampton Camera Club	Lantern Slide Competition. Subject— <i>Flowers or Still Life.</i>
3	Bowes Pk. and Dis. Ph. Soc.	Carbon Printing. Mr. Henry W. Bennett, F.R.P.S.
4	Royal Photographic Society	<i>The Negative in Portraiture.</i> Demonstrated. Mr. A. G. Field.
4	Glasgow Southern Photo. Assn.	Photographic News Prize Slides.
4	Rotherham Photo. Society	<i>Mounts and Mounting.</i> Dr. Paterson.
4	Leeds Photographic Society	<i>Little Things and Pictorial Photography.</i> Mr. W. D. Welford, F.R.P.S.
5	Edinburgh Photo. Society	<i>Pin-hole Photography.</i> Illustrated. Mr. A. P. Noble.
5	G.E.R. Mechanics' Institution	Carbon Printing. Mr. H. W. Bennett, F.R.P.S.
5	Cricklewood Photo. Society	<i>What can be done with a Hand Camera.</i> Messrs. Goetz & Co.
5	Everton Camera Club	<i>Carbon, the Amateur's Process.</i> Demonstrated. Mr. W. D. Welford, F.R.P.S.
5	Boro' Poly. Photo. Society	Rummage Sale of Members' Apparatus, &c.
6	Richmond Camera Club	Lantern Evening. Members' Slides.
6	Hull Photographic Society	Annual General Meeting.
6	Leigh Photographic Society	Members' Slides and Exhibit of Apparatus.
6	Röntgen Society	Exhibition Evening.
6	Batley and Dis. Photo. Soc.	<i>Taste and Selection of Subject.</i> Mr. Percy Sheard.
6	Southport Photo. Society	Members' Lantern Slide Competition.
6	L.C.C. Sch. of Ph.-Engraving	<i>Etching and Engraving.</i> Mr. W. Staig.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held March 29, the President, Major-General Waterhouse, in the chair. Mr. Gerald Bishop (Marion and Co.) showed the "Sinnox" system of daylight changing of plates, and exhibited a new folding pocket camera possessing the features of small bulk and ease of opening and closing.

Mr. William Gamble then read a paper, "Cameras and other Apparatus for Three-colour Work," in the course of which he subjected to a lengthy review the forms of taking and viewing instruments employed in trichromatic processes of colour photography. In speaking of exposures, he instanced the repeating back as the simplest and also the slowest method of making the three exposures. Methods

of synchronising the change of the plate with that of the filter were not reached a very practical stage in application to repeating-back. In reference to cameras in which three exposures were made simultaneously by three separate lenses, he explained that the difference in view point was a fatal defect of such systems, affecting the perspective of the three images. The plan adopted by Captain Laegee Davidson, under the name of the "Auto-shift Baseboard," obviated this difficulty, and provided a central position of the lens at each exposure. The ideal system in three-colour negative making "one lens, one plate," and Mr. Gamble described the various steps towards this result made by Ives, Du Hauron, and Sanger Shephard. In passing, a good deal was said on colour processes, and more also in reference to illustrations, without which a detailed report is of little use. A late hour was reached before the technical details of the three-colour apparatus were exhausted.

THE annual dinner of the North Middlesex Society took place Saturday last, the 25th inst., at the Holborn Restaurant, Mr. Ch. Beadle, President, occupying the chair. The toast of the evening was that of "The North Middlesex Photographic Society," was in the hands of Mr. Furley Lewis, who congratulated the members upon their recent exhibition and upon the work which they were accomplishing. The toast of the photographic Press was proposed by Mr. G. E. Williams, and replied to by Mr. George E. Brown (THE BRITISH JOURNAL OF PHOTOGRAPHY), Mr. A. Horsley Hinton ("THE Amateur Photographer"), and Mr. R. Child Bayley ("Photography"). The visitors, proposed by Mr. J. C. S. Mummery, was acknowledged by Mr. James A. Sinclair.

LONDON AND PROVINCIAL PHOTOGRAPHIC ASSOCIATION.—Meeting held Thursday, March 23. Mr. A. Mackie in the chair. The Secretary, Mr. R. J. Kindon, read a paper on "Pigment Papers," and demonstrated the use of commercial, ready-made gum-bichromate paper. The sensitising bath, he said, was made as follows:—Ammonium bichromate, $1\frac{1}{2}$ oz.; soda carbonate cryst. $\frac{1}{4}$ oz.; water 25 oz. One part of this stock solution was mixed with two parts methylated spirit to form the sensitiser, and, as was mentioned in the after-discussion, potassium bichromate must not be used in place of the ammonium salt, as it does not possess the required solubility in spirit. The paper dries in from five to ten minutes, and should be printed within 48 hours. An actinometer is used, there is no visible image, but Mr. Kindon said there was great latitude, and a golden rule was to over-expose rather than get too little, as over-printing could be corrected to a very great extent in development by use of longer time and treatment in a warm soda bath than usual before development. This soda bath consists of 6 parts soda bicarbonate in 100 parts of tepid water, and prints are immersed in it for five or ten minutes. Development, as Mr. Kindon demonstrated, was done either with a brush or by pouring a broth of sawdust repeatedly over the print. A brief washing in water completes the process, which was very successfully shown by the lecturer, and will no doubt prove a popular feature before other societies who can secure Mr. Kindon's services.

GLASGOW AND WEST OF SCOTLAND.—The usual monthly meeting of the Glasgow and West of Scotland Amateur Photographic Association was held in their rooms on Monday evening last. In the absence of Mr. Charles Kirk, his lecture was read by Mr. William Goodwin, on "Birds and Their Nests." For the photography of birds and their nests endless patience was required, and much time had to be given to the work. The results, however, amply rewarded the student for the time and labour devoted to the subject. Nests should be taken with the sun obscured, so that the markings on the eggs might be clearly shown. For the photography of the birds themselves the best plan was to place a heap of, say, brushwood about 15 ft. from the

est, and take the photograph with the camera all hidden in it, while the operator was some distance off. He found for this purpose an electric push and wire was better than tubing for the discharge of the shutter. For his exposures he found an ordinary half-plate lens gave the best results. With a telephoto lens, on the other hand, he had no success, as it seemed to give greater scope for movement. The student would find ample scope in natural history subjects like birds and their nests for scientific work. Mr. Colquhoun, who showed Mr. Kirk's slides, remarked how some were taken in difficult positions; one was shown in which the camera had to be tied to a tree 30 ft. from the ground to enable a nest to be photographed in an adjoining tree. To get another picture the subject was visited on five consecutive Saturdays before it was secured, while a considerable collection of eggs and seagulls of every description were secured during a visit to Ailsa Craig, which was shown to be full of bird life in all its stages.

JARROW AND DISTRICT CAMERA CLUB.—The annual meeting of this club was held last Tuesday in the club room, Ormonde Street, Jarrow. The Chairman, Mr. E. Penman, on behalf of the members, presented to Mr. J. A. Mitchell, who is leaving the town, a camera, in recognition of his services to the club during the two years it has been in existence. The Secretary, Mr. Walter Hanning, submitted the annual report, which showed that the income for the year had been £28 15s. 2d., and that there was a balance to the credit of the club. The membership was sixty-three, including eighteen ladies. The report was adopted. Mr. E. Penman was re-elected resident, and the vice-presidents elected were Mr. Rose, Dr. Jennings, Dr. McMurty, Mr. J. A. Mitchell, Mr. Henderson (Jarrow), Mr. Legge, Mr. W. E. Gibbon, and Mr. W. Hanning. Mr. Barrow has been elected secretary in place of Mr. Hanning, resigned, and Mr. Henderson, of Hebburn, was appointed treasurer.

SHROPSHIRE CAMERA CLUB.—An exhibition of pictures was formally opened on Tuesday evening in connection with the Shropshire Camera Club at the club room, Castle Street, Shrewsbury. The subjects were:—Landscape and Sea Views.—(1) Mr. J. Franklin; (2) Mr. W. D. Haydon; (3) Mr. H. M. Timpany; highly commended. Portraiture.—(1) Mrs. Haydon; (2) Mrs. Higginson; (3) Miss Parson-Smith; highly commended. Mr. W. D. Haydon. General Subjects.—(1) Mr. W. D. Haydon (pillars, Buildwas); (2) Mr. Dr. Moriarty; (3) Mr. F. R. Armytage. The judge was Mr. Edwards, of Hereford.

ULSTER AMATEUR PHOTOGRAPHIC SOCIETY.—A meeting of this society was held in the club rooms, The Museum, College Square North, last Monday evening. Dr. Cecil Shaw gave a lecture on his three-weeks' cruise to the Outer Hebrides in a 193-ton yawl. The lecture was illustrated by nearly 100 photographs, and included many excellent pictures taken in this delightful locality.

PHOTO ART CLUB, ABERDEEN.—The members of this club held their monthly meeting last week. An exhibition of slides of the Swiss Alps was the attraction of the evening. The following are the winners of the monthly competition for prints (architectural subject):—Mr. Clerihiw, Mr. Stephen, and Miss Dalgety. For slides: Mr. Bow, Mr. Clerihiw, and Mr. Dalgety.

THORNTON HEATH PHOTOGRAPHIC SOCIETY.—The recently-introduced method of "oil-colour printing" was demonstrated by Mr. R. McKenzie to the members of this society on Tuesday of last week. The process, which is hardly correctly indicated by the title, bears a strong resemblance to collotype, and is one of the many depending on the action of light on a bichromated colloid. In the hands of the lecturer a number of capital prints were obtained, closely re-

sembling carbon in appearance, but the chief merit of the process, in the eyes of many, and particularly those addicted to "gum," will lie in the fact that an almost unlimited amount of personal control can be exercised. The following is a brief outline of the process as given by Mr. McKenzie:—Any sort of paper is taken, whether rough, smooth, or tinted, provided it is of not too soft a texture. It is then coated with hot gelatine solution (1 oz. of gelatine to 5 to 8 oz. water) by means of a broad, flat brush, and hardened by immersion in formaline (40 per cent. solution to 20 oz. of water). The sensitising bath is bichromate potash, 1 in 20, the paper either being dipped or the solution brushed over the gelatinized surface. Printing is effected in the usual way, until all details except the highest lights are well out. The print is now washed in cold water to discharge the bichromate stain, soaked in warm water until the image appears distinctly in relief, and surface-dried. The state of things at this stage is that the high-lights, and in proportion the half-tones, having absorbed more water than the shadows, possess a higher relief. Any suitable oil-colour is then taken, mixed with poppy-oil, or megilp, and a little gently smeared over the surface in every direction. Mr. McKenzie used a finger-tip for the purpose. A roller squeegee is then rolled over the pigment, always in one direction, removing the paint first from the high lights and next from the half-tones, and so on, owing to their relative greater protrusion and resisting or repelling action to the oil-colour. Brushes can also be brought into requisition, and by their aid shadows may be strengthened or reduced, high-lights introduced, and defects touched out; in fact, there seems hardly any limit to the various modifications which might be made.

RICHMOND CAMERA CLUB.—At the weekly meeting of this club on Thursday of last week a demonstration in "Auto-pastel" was given by Mr. Oetzmann. This new process, introduced by the Autotype Company, was followed with much interest by the members present. The lecturer stated that the process was analogous to gum-bichromate, yet the principle was different, inasmuch as the pigment coating becomes insoluble after exposure, and development was effected in the hot-water bath by means of a flat camel-hair brush, with which the surface of the print is abraded and the latent image revealed. Mr. Oetzmann developed several prints, and showed the complete control over the process which the use of the brush gave the operator. He also explained the opportunity of local treatment and the special care which can be bestowed on particular portions of the picture. Further advantages claimed for Auto-pastel were that it was a permanent pigment printing process without transfer, with a range of colours through black, blue, green, and brown to red tones, the rapidity of the printing being about the same as ordinary carbon.

WATFORD CAMERA CLUB.—The weekly meeting of this club was held on Thursday of last week. The evening opened with the presentation of a gold plaque to Mr. W. Linley for the best exhibit in the members' classes at the last exhibition, given by the president, Lord Hyde. After the presentation a competition of "Views on the Grand Junction Canal" resulted in Mr. W. J. Edmonds, sen., being declared first, with Messrs. W. Bullock and A. W. Hodgins bracketed second.

BLAYDON AND DISTRICT CAMERA CLUB.—The members of this club held their annual exhibition on Tuesday night last, in the U.M. Free Church Schoolroom, Blaydon. The judges were Mr. Arthur Payne, F.R.P.S., of Gateshead, and Mr. C. Hughes, of Newcastle. The awards were as follows:—Photographs: Class 1—W. A. Bagnall, 1; J. W. Dodds, 2. Class 2—E. J. Patterson, 1; Edward Batey, 2. Lantern Slides—Wm. Steele, 1; Walter Tate, 2. There was also an exhibition of federation lantern-slides.

SOUTHAMPTON CAMERA CLUB.—Mr. W. R. Kay, one of the promi-

ment workers of this society, gave a lecture to the members on Monday last, which should have a good effect on the artistic preceptions of his hearers. His subject was "The History of Painting," and consisted of a review of the great masters of the art from Raphael to Romney. Being illustrated throughout by excellent lantern slides, example made as good impression as precept, and the influence of the lecture should become apparent later in the work of the members.

News and Notes.

PICTURES from the Barnet Competition.—Messrs. Elliott and Sons, Ltd., announce that a selection of the prize pictures entered in the £500 competition, which recently closed, will be on view at their stall in the trade exhibition at the Portman Rooms, Baker Street, opening on April 7.

NEGOTIATIONS are in progress for the amalgamation of those two well-known and old-established societies, the Society of Arts and the London Institution; and there is every probability that this amalgamation will very shortly be carried out. A scheme has been prepared by a joint committee, and it only remains to be submitted to the general body of the members, whose assent in all likelihood will be quickly given. The idea is that the London Institution should sell its house in Finsbury Circus, that the Society of Arts should leave John Street, Adelphi, and that the joint concern should build new premises in Kingsway or some other more westerly thoroughfare.

THE biograph pictures at the Empire Theatre, Leicester Square, London, are now a very strong feature of the programme. They are extremely up-to-date, as well as being good photographically. As an instance of this, an admirable film showing Earl Roberts presenting the Queen's shamrock to the Irish Guards on St. Patrick's Day was exhibited the same evening.

ONE of the few remaining links with the palmy days of wood engraving has been broken by the death, in his eighty-eighth year, of Mr. Edward Dalziel. In association with his late brother, George, he was for over half a century closely connected with the art of high-class illustration in this country, and has observed the gradual ousting of the engraver by photo-mechanical methods during that period. He was a contemporary of Tenniel and Keene, at the Clipstone Street Life School, and in the course of time many notable artists worked for the Brothers Dalziel, and drew on the wood blocks for the numerous books they undertook to illustrate, Leighton, Millais, Poynter, Burne-Jones, Whistler, Watts, Landseer, Holman Hunt, and Rossetti being among the number. Mr. E. Dalziel, who was one of the finest of wood engravers, gave early encouragement to many black and white artists who have since become famous.

THE Stereoscopic transmitter, made by Theodore Brown, of Salisbury, is now supplied at the reduced price of 7s. 6d. instead of 10s. 6d. as hitherto. The finish of the accessory qualifies it for attachment to a camera of the highest class and the reduced price should popularise this form of stereoscopic work.

DEATH of C. S. Abbott, President of the American Aristotype Co.—Charles S. Abbott, president of the American Aristotype Company, Jamestown, New York, and vice-president of the Eastman Kodak Company, died very suddenly at midnight Wednesday, March 1, while staying at Oak Lodge, his country residence 13 miles from Enfield, North Carolina. Death was caused by neuralgia of the heart. Mr. Abbott's name was probably better known in America than in England through his connection with the well-known Aristotype paper, which he brought into almost universal use in that country, and made extremely popular in this. His loss will be felt by all, both those connected with his company and the vast number of photographers to whom he was known throughout the photographic world.

Correspondence.

*** We do not undertake responsibility for the opinions expressed by correspondents.*

THE EDINBURGH PHOTOGRAPHIC CLUB AND THE SCOTTISH FEDERATION.

To the Editors.

Gentlemen,—As a notice has appeared in the photographic press to the effect that the Edinburgh Photographic Club has joined the Scottish Photographic Federation, and as the club is apt to be confused with this society. I think it well to point out that, while it consists of not more than forty members, all of whom are probable members of this society, it in no sense represents the latter. As announced in the Press, it resolved to join the Federation, but at a subsequent meeting it rescinded this resolution.—Yours faithfully

J. S. McCULLOCH,

Hon. Sec. Edinburgh Photographic Society.

3A, North St. David Street, Edinburgh.

March 22, 1905.

MERCURY-VAPOUR LAMPS.

To the Editors.

Gentlemen,—My attention has been drawn to a note in your issue of the 17th inst. re Mercury Vapour Lamps.

This note is surely written without a full consideration of the condition under which the modern types of mercury-vapour lamps are operated, but it should be sufficient for me to point out here that should the lamp break, the mercury vapour within it would immediately be subjected to atmospheric temperature and condensed, and insufficient vapour would escape to form so much as a healthy tonic.

During experiments I and my assistants have frequently been standing within a foot of lamps whilst they have been purposely burnt out with an excess of current, but, in spite of the presumably abnormally high temperature of the mercury at the moment the lamp broke for the very simple reason given above, never with the slightest effect.—I am, yours very truly,

C. ORME BASTIAN.

The Bastian Mercury Vapour Lamp, Ltd., Bartholomew Works, Kentish Town, N.W.

March 24, 1905.

Gentlemen,—We note in your issue of March 17 a very misleading paragraph, headed "Mercury Vapour Poisoning," in which it is stated that the breakage of a mercury-vapour lamp tube might be the cause of death to the operator by reason of the poisonous nature of the vapour contained in the tube.

We trust you will allow us the opportunity of publicly refuting this statement, inimicable both to our interests and those of the principle upon which the mercury-vapour lamp works.

The vapour which serves to conduct the current would, upon breakage of the tube, immediately condense into liquid mercury, the vacuum being destroyed, and it is therefore impossible, under any conditions, for harm to result from such a cause. Tubes have occasionally been broken by accident in the Cooper Hewitt laboratories and workshops, but, for the very simple reason given above, never with the slightest evil consequence to the operators.—Yours faithfully,

G. T. FAIRBROTHER.

The British Westinghouse Electric and Manufacturing Company, Ltd., Westinghouse Building, Norfolk Street, Strand, London, W.C.

March 25, 1905.

[Our note expressed an apprehension which we had heard put forward, and which we understand had some foundation in fact.

We are glad to publish the above assurances that nothing of the sort can take place in the modern constructions of lamp.—EDS., B.J.P.]

THE SHOP AND HOUSE DUTY ACTS.

To the Editors.

Gentlemen,—Mr. Sander in his letter to you states that he does not live on the premises he occupies as a professional photographer and dealer. Under those circumstances he is not liable to pay duty at all. The Acts apply only to inhabited houses. He should, therefore, refuse further payment and apply for the repayment of any sums he may have erroneously paid. If he will correspond with me I shall be happy to give him information.—Yours truly,

G. BROWN.

23, Tettenhall Road, Wolverhampton, March 27, 1905.

By the death of Edward Wuestner, a notable figure in the American photographic field has been removed. In 1882 he went to work with the St. Louis Dry Plate Co., and later started the Eagle Dry Plate Co., supported by the late G. Gennert. When the Eagle Company went out of business he started the Wuestner Dry Plate Co. Mr. Wuestner died March 9, aged 63.

THE "Compensator" Negative.—In the current number of "The Photogram" an ingenious method of controlling negatives of difficult subjects is the theme of an excellent editorial article. The method has been devised by Mr. Newton Gibson, whose interesting candle-light studies are well known, and, stated in his own words, is as follows:—"First expose a plate which gives clear glass for the shadows, with the glass side towards the lens, giving a very short exposure for the lights only. Develop, fix, and dry; then put back again into the dark slide, to the same place as before, with another (unexposed) plate, film sides together, and give a full exposure for the shadows. If the first negative be of the right density, the second will develop in perfect gradation, and with a good stereoscopic effect." The plan appears excellent, but is necessarily confined to subjects that show no movement. The illustrations accompanying the article amply demonstrate all that is claimed for the method of employing the "compensator" negative, which includes the prevention of halation without backing, the control of strong contrasts, skies truly rendered without colour screens or double printing, improvement of colour-rendering with ordinary plates, and control of gradation. Truly a comprehensive list of the ills that photographers are subject to. An additional method of employing the compensator for existing faulty negatives is also suggested by employing a film positive made by contact from the imperfect plate, and then used with it when making prints. Other ways of employing the compensator negative will doubtless suggest themselves, and, with this object in view, the Editors of "The Photogram" are offering prizes for the best work showing the application of the treatment.

The catalogue of the City Sale and Exchange, 90-94, Fleet Street, London, E.C., newly issued for the coming season, describes and prices an extraordinary variety of apparatus, representing the requirements of the photographer for every class of work. A number of these goods are the firm's own "Salex" specialties, and the list is certainly one in which the purchaser can pick and choose to his heart's content.

It is with regret that we have to record the death of Dr. Eugen English, of the Technical High School, Stuttgart, after a long illness. He was the author of a well-written text book, the "Compendium der Praktischen Photographie," and the founder of the "Zeitschrift für Wissenschaftliche Photographie," a monthly journal dealing exclusively with the higher technical and photochemical questions.

Answers to Correspondents.

- *.* All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.
- *.* Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.
- *.* Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & CO., 24, Wellington-street, Strand, London, W.C.
- *.* For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.

STEWART.—The Pictorial Stationery Company, Limited, 23, Moorfields, London, E.C. We think you have a clear claim for reproduction fees.

TONING BROMIDES.—I have been asked to do a dozen cabinets as specimen enclosed, a toned bromide. Will you give me the formula and how to work same to that colour? I have tried the uranium, and they go so awfully yellow and fade out.—(GEORGE.

Bleach the well-washed prints in solution of potass ferri-cyanide ($\frac{1}{2}$ ounce), ammonium bromide (300 grs.), water (20 ounces), and after well washing darken in a solution of pure sodium sulphide (30 grains in 10 ounces), finally washing thoroughly. You can obtain toning solutions ready made, and perhaps this is your wisest course. See this week's advertisement pages.

MRS. A. H. LUCAS. —Mica has been used before as a substitute for glass, but there are drawbacks to it, which we doubt whether you have overcome. Possibly you might obtain something for your patent by advertising it, but we cannot suggest any other way.

RETOUCHING AND SPOTTING.—(1) Please give me your opinion as to the commercial value of work on accompanying specimens of retouching and spotting as shown on the print in uniform. (2) The operating is my own, and in making application for situation I wish to know the remuneration I might reasonably expect for such work. I have had eighteen years' experience in all branches, but have not worked for an employer since 1896—hence the queries herein.—LIMERICK.

(1) There are two photographs in uniform. The c.d.v.

shows very good retouching as far as likeness and fine touch are concerned, and the attention to the eyes proves that you are skilled and experienced; but for our taste—the sitter being a man, and presumably weather-beaten—the effect is not broad enough, and therefore lacking in softness. In the cabinet oval—a very easy subject—the general result is good, but you have increased the width of the nose and rendered the eyes too beady. The gentleman with beard displays the best work, but the wrinkles on the forehead are too obtrusive and the touch is too pretty for a man of this age. Looser and softer working would have greatly increased the value. The chief object in art is to conceal art—aim always for breadth and effect. The tight, egg-shell stipple is admired by the majority, but deplored by the sensitive minority, and the minority are more often correct than not. Just a touch of additional knowledge and you would be a really artistic and first-class retoucher. (2) As retoucher only you should command about £2 per week, but as retoucher and operator combined, and with your long general experience, if of the same class of finish, you should be worth considerably more.

OPINION WANTED.—I am taking the liberty of sending you a few prints, to ask you what salary I might ask when applying for a situation. I have had eight years of P.O.P. printing and two years of carbon, besides mounting and assisting generally. Having worked for one firm all the time I do not know what salary is generally given.—P. O. P.

The specimens sent are good ordinary commercial work, such as is usually paid for at the rate of about 15s. to 18s. a week. We would suggest that you make yourself proficient in platino-type and collodio-chloride printing, also in retouching, then you could command a higher salary.

GUINNESS, GEORGE.—We cannot say. We believe there are no regular makers, but an advertisement will probably bring you into touch with parties disposed to sell.

COPYRIGHT QUERY.—We have recently had a picture sent us from the U.S.A. which is copyright there, but not in this country. (1) Can we copy it and copyright the copy? (2) If we do this can we prevent anyone else if they obtained a similar print from copyrighting it? (3) Can we prevent the importation of copies from the U.S.A. of the same subject? (4) Can we enter the name of the man who makes the copy as the artist, if we do not know the original artist's name?—U. S. A.

(1) As the United States is not a party to the Berne Convention you can legally copy the picture and make your copy copyright. (2) No, certainly not. (3) Decidedly not. (4) No.

MATT SURFACES.—Kindly tell me how many grains of silicate of soda I must put to six ounces of bromide emulsion to give it a dead matted surface for coating paper, or of sulphate of barium.—J. HARRIS.

We regret that we cannot state how to use the silicate of soda. Some time ago we made a lot of experiments on this point, and could never get a satisfactory grain with it. As a rule, for making matt paper, a matt baryta paper is used, and the quantity of the gelatine in the emulsion is reduced. If sulphate of barium is used it would be as well to form it in the emulsion, and if 30 grains of barium chloride were added to six ounces of emulsion and then 15 grains of ammonium sulphate, dissolved in a little water, added slowly with constant stirring, a very fine precipitate of barium sulphate will be formed; the emulsion must be washed after this, or this addition may be made before the emulsion is washed in the usual way. Rice starch is frequently used for the same purpose, and from 10 to 15 grains per ounce is quite enough.

LENS.—(1) Is there any difference between an anastigmat and an R.R. lens, and has the former any advantage over the latter for outdoor groups, etc.; and if so, will you kindly say in what way? (2) Also, what type of lens is really the best for enlarging?—UNCERTAIN.

The difference between an anastigmat and an R.R. is that the former is constructed of special glasses, which enable a very much flatter field to be obtained at a given aperture; in other words, the anastigmat will work at a larger aperture over a given sized plate than an R.R., and as this means, obviously, reduced exposure the anastigmat is to be preferred for all classes of work. (2) The anastigmat is the best type, as this has a specially flat field, and therefore does not require stopping down for sharpness, and as it is also better corrected for anastigmatism it really gives better definition.

J. T. HACKETT.—Stout canary paper, 36 by 21, is quoted by Marion and Co., Soho Square, at 5s. per quire.

STUDIO.—I should feel greatly obliged if you would give me your opinion on this studio, which I propose building (rough sketch enclosed). There is no choice as to light, which I am bound to get from the one direction, as you will see. We find from previous experience that we shall be bothered by the sun shining into the studio, more especially in the summer months, so would ask (1) Are the proportions of studio good? (2) Would you advise both sides of studio to be glazed? Boundary wall on one side is 4ft. 6in. high. (3) Would obscured glass be any advantage over clear glass, which would, of course, be covered with waxed paper in the summer?—CHAS. COOK.

(1) The proportions are good. (2) If both sides were glazed it would be of some advantage, as you could then use the, nearly, west side in the morning, and one, nearly, east side in the afternoon, thus greatly avoiding sun trouble. Instead of 18ft. of glass 16ft. will be sufficient. (3) No great advantage if the glass be obscured, when necessary, with waxed paper. We should advise you to get Bolas's book on "Studio Construction," published by Marion and Co.

COPYRIGHT.—Some time ago I purchased a business, including large number of copyright negatives. The solicitor's agreement distinctly states "negatives and the copyright attached thereto." Will it be necessary to re-copyright them, or does the original copyright stand good?—COMPLEX.

The copyrights hold good, assuming that they have been registered at Stationers' Hall.

NOTICE.

Several replies are held over for insertion next week.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

Glass in the Studio Roof. Now that the brighter weather has come again photographers are cutting down exposures or reverting to plates of ordinary speed. A little attention to the outside of the roof would in most cases result in a further halving of the exposure. The fogs with the deposition of soot during the winter reduce the amount of light admitted very considerably, and the cleaning of the glass is a matter which might well be seen to periodically, so that all the light available might be admitted. It may be argued that the grime acts as a diffuser, softening the brighter light, but it is always an advantage, we think, to have more light than is requisite, and to cut it down by means of diffusing screens in the studio. These screens may be modified or dispensed with on those dull days which come without warning at all parts of the year; but an outside coating of grime cannot be removed so readily. In the building of new studios attention should always be given to the means, both of cleaning and repairing the roof. We recently saw a glazier replacing a pane of glass in a studio roof, simply kneeling on a board placed across the sash-bars, with only two feet behind him a drop of 50 ft. to a cement yard. The position of this roof made it practically impossible to clean the glass either on top or sides, and very dangerous to replace broken panes.

British and Foreign Dry Plates. A tribute is paid to the sensitive photographic materials of British production by the "Times" in its financial and commercial supplement of Monday last. Discussing, as the article purports to do, the influence of Continental and other foreign trade on the photographic industries of Great

Britain, is a profitless task when there are no figures to show its extent—the only figures which the "Times" puts forward it quotes from our issue of February 24 last—and hence the chief argument is the very tenable one that the merits of the British dry plate are so patent in comparison with the German article that the very approximate figure of £300,000 for Germany's entire output of plates is probably quite large enough. It is a case of quality dominating the market. "It may be confidently asserted," says the "Times," "that in the highly important respect of speed or light-sensitiveness no German plate equals one or two well-known English plates which might be mentioned. Then as regards the orthochromatic or colour-corrected quality of plates, which has lately been so much in demand, and which represents so large an improvement that the orthochromatic plate promises to supplant entirely the ordinary or uncorrected plate, there seems little doubt that the superiority of several of English manufacture has been fully proved, especially if price also be taken into account."

Nitro-cellulose.

A paper was read on Monday last before the Society of Chemical Industry on "The Formation of Sulphuric Esters in the Nitration of Cellulose and their Influence on Stability." The authors, C. Napier Hake and R. J. Lewis, sought to establish the formation of sulphuric cellulose compounds when cotton is nitrated with a mixture of nitric and sulphuric acids. A number of experiments showed that sulphur was a constituent of the nitro-cellulose, but, as transpired in the discussion, the formation of such compounds was shown by Cross and Bevan in their paper of 1901, in which they also pointed out that an essential condition favourable to the retention of sulphur was a short duration of exposure to the mixed acids. The authors argued that the sulphuric ester was a cause of instability of the nitro-cellulose, but this argument was actively questioned in the subsequent discussion. The subject, though undertaken in the interest of explosive manufacture, bears on the preparation of nitro-celluloses for celluloid making, and the further papers promised by the authors may contain more definite data.

Measuring the "Hardness" of Gelatine. A method of making comparative measurements of the rigidity of gelatine jellies is described by a writer in the current issue of the "Oil and Colourman's Journal." The apparatus consists of a metal cylinder terminating below in a capillary glass tube containing mercury. The fluid jelly is poured into the cup, and, when it sets, distortion of the gelatine due to pressure is shown by the movement of the thread of mercury. The pressure is obtained by a

rubber bag filled with water, and the apparatus is so arranged that the "rigidity" of the gelatines can be expressed by a figure calculated from the pressure reading. The method may perhaps be worth notice with a view to testing samples of gelatine for emulsion making or photo-mechanical processes.

Fire Risks.

A volume just published as a translation from a German work possesses some interest for photographers and the photographic trade, inasmuch as its subject is the danger and prevention of fire and explosion. Written for the information of insurance officials and others similarly concerned in accidents of the above character, its aim—a natural one, no doubt—seems to be to magnify the opportunities for fire which certain industrial operations may offer. Thus the statement in reference to collodion, that "it is a source of danger in photographic studios," is calculated to create the impression that the collodion process is commonly employed by professional photographers. The reference can easily be misread to mean more than it actually states, and it is not difficult to imagine an insurance official endeavouring to make capital out of it. The list of substances which the insurance company is to put on its black-books is a very long one, for the author's zeal in his object leads him to see danger everywhere. We naturally turned to see what he has to say for celluloid as a spontaneously inflammable body in view of the recent reports from the Continent giving celluloid a bad character in this respect. However, we are glad to find that the author takes the same view of this matter as that expressed by ourselves some weeks ago in this column—viz., that the mistrust of celluloid is to be attributed to a product of defective manufacture and wrong composition. It is pointed out that badly washed, impure celluloid may be caused to detonate by very gentle heat such as the radiant heat of a stove or an electric incandescent lamp. Celluloid as used for photographic film must, by the very exigencies of the case, be the purest obtainable, and therefore the alarmist reports which occasionally gain notoriety may be held inapplicable to sensitive materials of which celluloid is the support.

* * *

Society Excursions.

The programmes of club outings that are now being sent to us every week point to a revival of outdoor activity amongst photographic societies in all parts of the kingdom, in spite of the frequent assertions made that "society excursions are a thing of the past." Doubtless, to the advanced worker, there is not much to be done in the way of serious picture making on these excursions, which more often than not resolve themselves into pleasure trips, the principal function of which is "high tea," but to the beginner much practical benefit may be derived, not only from observing the methods of the more experienced workers in the field, but also from a comparison of ideas with other beginners. It may be true that as soon as the amateur photographer becomes expert in his art, he strives to specialise and avoid the company of his fellows when in search of pictures, but fortunately there are many such experts who, in addition to having reached a high standard in individual work, have still, as members of societies, recollections of their own early struggles, and are not adverse to lending a helping hand to their less advanced companions. To such members the beginner naturally turns when on society excursions, and the success of the outing, from a photographic point of view, is usually in exact ratio to the endurance of these sacrificing individuals. The presence of one or more advanced workers in the company often does much to save a needless expenditure

of plates on the part of the novices, besides doing much to raise the tone of the annual exhibitions of members' work.

The Privileged Foreigner.

The pertinent question asked in the House of Commons last week by Sir George Bartley, who invited the Minister for War to state whether, "during the visit of the German Emperor and his staff to Gibraltar, only those parts of the fortress would be shown which are open to British subjects, and whether the same rules as to photographing the fortress or any parts of it would be upheld which were rigidly enforced on British subjects," met with the somewhat unsatisfying response from Mr. Arnold-Forster that "subject to the regulations, the responsibility rested with the general officer commanding, whose discretion it was not proposed to interfere with." Whether or not the officers of a country which is building a fleet which may be used against us were given facilities that are not granted to loyal subjects of the Crown has not transpired, but the fact remains, and has often been pointed out in the lay Press, that the officials in Government buildings and dockyards in this country are only too prone to permit foreigners who visit such institutions in an official capacity every opportunity of using the hand camera under circumstances that would result in the immediate expulsion of any enterprising Englishman who attempted to do the same thing.

An Unsuspected Fault in Focal Plane Shutters.

An unsuspected cause of faulty negatives produced with focal plane shutters of a certain type has recently been brought to our notice. The negatives in question showed an evenly graduated decrease of density or exposure from top to bottom, incompatible with the subject rendered—i.e., the foreground portion of a landscape received considerably less exposure than the nominal exposure warranted, and the sky portion considerably more. An inspection of the shutter, which was of the enclosed spindle type, revealed the fact that the width of the slit altered during the exposure. This was particularly apparent when the smallest slit was used, and could be easily observed while the blind was being wound up. Partial dissection of the working parts disclosed the cause of this defect. The pulley bands connecting the upper half of the blind with the lower were of a stouter substance than the blind material itself, and, while being wound up, accumulated on the ends of the spindle to a greater degree than the blind on the remainder of the roller, the result of this being that, as the shutter was wound up, the lower blind would be drawn nearer to the upper, thus decreasing the slit. Releasing the shutter reversed the action, resulting in increased exposure for the bottom of the plate—i.e., the sky portion. This fault may be an isolated case, but is worth placing on record, and, of course, it would not apply to shutters in which the width of slit is regulated by a cord, or chain, or to the double roller patterns, but it would be as well for all users of focal plane shutters to carefully test them, and ascertain, preferably with the smallest slit in operation, if the aperture remains constant throughout the exposure.

Replicas of Diffraction Gratings.

The advantages of the diffraction grating over prisms for spectroscopic work is pretty generally known, and the best are those ruled by Professor Rowland, of the John Hopkins University. Unfortunately, however, the cost of these is considerable, particularly those ruled on concave speculum metal. Some years back Mr. Thorp, of Manchester, was enabled to obtain casts in celluloid of a plane

grating, which are sufficiently satisfactory for general work, but for extreme accuracy they cannot be depended upon, as there is unequal contraction of the film, and disturbing influences set up by the difference in refractive index of the celluloid and the glass upon which they are mounted. Now we see that Mr. F. E. Ives recently read a paper before the Franklin Institute, U.S.A., in which he stated that he had made considerable improvements by making the casts in a harder and less elastic material than celluloid, and by putting them face down upon the glass and forcing them into optical contact therewith, so that the perfect plane of the diffracting surface is preserved, and by sealing them up under another plane glass with a balsam mixture having the same refractive index as the casting material, so that the perfect parallelism of the transmitted rays is insured, and at the same time the grating is protected from injury. There is a very slight but even shrinkage of the cast, but after measuring up a large number it was found that it never amounted to more than four or less than two in a thousand, and that by easily established conditions it could be kept very close to either of these figures. Under the conditions finally settled upon, the replicas come out uniformly about 15,050 lines to the inch, and with so little distortion that an expert spectroscopist, working with a large Hilger spectroscope, declared that he could discover no difference in definition between an original Rowland grating and one of these replicas.

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION AND ITS WORK.

THE pleasant gathering of the Committee of the Professional Photographers' Association and other friends of the Association, which is briefly reported in another column, coincides almost to the day with the fourth anniversary of that important gathering which was organised by THE BRITISH JOURNAL OF PHOTOGRAPHY at Anderton's Hotel, Fleet Street, E.C., on March 28, 1901, and resulted in the formation of the Association. Since then much water has flowed under the bridges, and it is now opportune to review briefly the results of that movement to bring the members of the photographic profession together in co-operation for their common benefit.

The programme suggested at that meeting for such an institution to undertake was extremely ambitious and comprehensive. It included many items which would obviously require many years of hard work to carry out; it included some which could only be carried out if the Association should become actually representative of a large majority of the profession throughout the country, and even the least ambitious of the projects depended upon organising ability of the kind that up to then no attempted combination of photographers had shown signs of possessing. It was freely prophesied by many that the new Association would not survive its second year, and, possibly, the previous experiments in the same direction justified the prophecy. The Association has, however, not only survived its second, but is just entering upon its fifth year, and those most capable of judging what its prospects are—those upon whose shoulders the brunt of the labour has fallen—are as enthusiastic as at the commencement in their belief that by the co-operation of the fraternity substantial benefit is to be derived by their community.

In some directions the Association has not answered the expectations of some of its founders. It has not been able to dictate who shall and who shall not produce photographs for sale, or the price or a minimum price at which they shall be sold, and as no one among the many thousands who are equally interested in the matter has produced a

practical suggestion how it is to be done, it is reasonable to presume that it is not possible. The Committee made a valiant fight against manufacturers, newspaper proprietors, and others offering enlargements free, or at prices which might appear to be cheap to those to whom an enlargement is simply an enlargement, by the only means in their power—a strong and dignified protest against an unwarrantable form of competition. That movement, however, did not achieve all it aimed at; it was not expected that it would. The grocers, a body far greater in number and with powerful trade organisations all over the country, with local as well as general means of making their influence felt, have no less signally failed in restricting the sale of their principal commodity, tea. In one respect the Association's efforts generally succeeded. In many cases the absurdly false statement that the article offered was similar to that for which photographers charged two to three guineas was withdrawn in compliance with the protest.

With regard to the free-portrait swindles, the Association has issued a general invitation in our columns to submit cases of this form of fraud with a view to their initiating or supporting legal proceedings against the offenders. Many replies have been received from photographers in the provinces whose business and reputation suffered, but in the cases where there appeared a reasonable chance of conviction it has been found that not a single individual of those complaining has had the energy and perseverance to obtain *prima-facie* evidence of a specific case of fraud to enable the Association to proceed.

In another direction the Association has not yet fulfilled the hopes that were formed of it by some. It has not been able to deal with the evil of price-cutting among photographers themselves, which undoubtedly exists to a lamentable extent in some localities. But this should not be counted as a failure for which the Association, as it is, is to blame. In a business which is open to every one there is no legal method of coercion with regard to prices or in other matters, and there is no force, legal or otherwise, that the minority can exercise over the whole body. But if the majority of a profession are banded together to protect their mutual interests, if that majority cannot exactly coerce the minority, at least there are means of making it very unpleasant for a minority which refuses to play the game according to the ordinary rules of fair play.

Let us turn to the brighter side, the valuable work the Association has done and is doing. One of the bitter complaints made at the initiatory meeting was the exorbitant rates charged to professional photographers for fire insurance. In that direction the benefit of co-operation at once manifested itself. Arrangements were made whereby members could remove their existing policies to an office of first-class reputation at a premium 20 per cent. lower than that previously paid—a substantial relief, which in many cases must very much more than exceed the amount paid as subscription to the Association.

In photographic copyright matters the Association holds an unchallengeable claim to the gratitude of the whole photographic community. The present Copyright Act, intricate in its drafting, and further complicated by numerous decisions in the Courts, is something for most photographers to blunder over at every turn. The Committee of the Association, including as it does the holders of some of the most valuable photographic copyrights in the kingdom, who have had to fight for their rights, constitutes an authority on questions involving photographic copyright whose opinion is of extreme weight. This opinion is available to any member who chooses to ask for it. Moreover, the handbook issued to members contains a compendium of copyright law and a guide to dealing with

copyright matters so concise and comprehensible that it is difficult to believe that any one who refers to it can act wrongly in any ordinary dealings in which copyright is involved. Other matters of professional practice are equally well treated upon in the book, and there is the same right for members to receive the opinion and advice of the Committee upon any subject which can reasonably be included in the business side of photography. This privilege of membership is extensively made use of. Some hundreds of letters are received and answered during each year. Many of them, of course, contain simple questions which can be answered in a moment; but, on the other hand, legal points are often involved, which require mature consideration and possibly reference to the Honorary Solicitors. When a case arises in which expensive law proceedings seem the only way of settling a difficulty, the advantage of being able to take the opinion of a body of business men acquainted with the technicalities and practice of professional photography, having legal assistance, and in a position to view the matter impartially and broadmindedly, is an undoubted benefit. It is an established fact that in many instances the advice given has resulted in satisfactory settlement without recourse to law, and in others the information supplied has prevented the initiation of proceedings when the possibility of success has been remote, and useless expenditure when the likelihood of obtaining the amount of the claim and costs has been small. In another way connected with law the Association is doing extremely useful work. It is notorious that it is difficult to obtain a decision from a judge in a case which turns upon the value or quality of photographs. Rightly, a judge generally discerns that in these matters he is not a judge, and more frequently than not he adjures the parties to come to an agreement. In a case of the kind a few months back, the Judge of the Reading County Court, with the consent of the parties, appointed the Committee of the Association arbitrators, and several times recently in disputes between members and other parties, the offer of the Committee to arbitrate has been accepted, and the decisions given have satisfied both sides. The method of settling differences between photographers and their customers or dealers, trade printers or enlargers, etc., thus now open, is in itself an

invaluable institution, and the cost is a trifle compared with proceedings in the Courts.

The assistants' certificates scheme recently published has been one of the Committee's severest labours. As a present to the body of professional photographers, it should have been received with grateful enthusiasm. That it has not is characteristic of that terrible apathy to common interests which is the besetting sin of the profession. Our columns, from the earliest numbers, testify to the desire of both employers and assistants for that which is now provided. The comprehensiveness of the scheme must be acknowledged, and that the greatest credit is due to those who have performed the work is undoubted. To what extent it will be a success it is too early to forecast, but even if in the present form it is not universally acceptable, we have no doubt that in the revision which it is to receive after a year's trial, it will be amended wherever found necessary. The Committee have invited and are anxious to receive criticisms and comments.

The other fields of the Association's activity we must pass over or deal with very briefly. A watchful eye is being kept on the attempt now being made to alter the law of copyright. Photographers' interests are at stake, and at the proper time will be asserted. Much is being done to educate members as to the value of rights of reproduction and how to obtain reasonable fees, and information is collected and is available to members as to dealings with the press agencies. The provision of means for professional photographers to exhibit their work has not been neglected. Successful exhibitions were held last year during the Convention at Derby, and the year before at Perth.

It can hardly be disputed that the Association makes a good record for only four years of existence. That its membership has not reached thousands should be a cause of astonishment, but that the whole of the work is performed at an annual cost of about £140 reflects creditably upon the management. It may be some of the members have not been able to trace a direct return for their small outlay of 5s. per annum, but it is indisputable that collectively the members have each year received more than £140 worth of direct benefit, to say nothing of the good work done for the profession generally.

ADVERTISING AND THE PROFESSIONAL PHOTOGRAPHER.

III.

HAVING dealt in the two previous issues of the B.J. with the general basis of a photographer's advertising, and given some examples which may prove useful as suggestions for individual cases, I must draw these notes to a conclusion with a consideration of certain other features in the maintenance of dignified publicity.

Railway Station Advertising.

In some parts of the country the display of showcases on the railway stations is a form of advertising frequently seen, and, when well done, it is, without doubt, one likely to do good. Often, though, the effect is the reverse of good; a case is put in an exposed part of the station, so that for several hours daily it is open to the sun's rays, the consequence being that the velvet or other lining fades, the paint cracks, and the wood, if not well seasoned, warps to such an extent that damp gains access to the photographs. The cases, too, are generally crowded—a matter that has been already dealt with in connection with the studio itself. Even when no fault can be found as regards the case and its contents, the outlay is often largely wasted

on account of the station chosen being unsuitable. A certain photographer practising in a small town which we will call A., situated twenty miles from London, has a showcase on a station of a much larger town, B., ten miles nearer London. Now, the number of visitors from B. to A. is small; the residents of B., if they are not satisfied with the good photographers in their own town, will certainly not travel to A. when London, with countless other attractions, is within the same distance. Whereas, had the case been put on any station within, say, five miles of A., it would have done much more good; its argument would, in effect, have been, "Why travel to B., or still more distant London, when there is a good photographer at A.?"

Another form of advertising is that of taking space in the **Street Display Boards** now to be seen in many towns. These are large glass cases in which there are about a score of tradesmen's advertisements, highly coloured, and with a lavish use of gold leaf. At first sight these cases appear to serve much the same purpose as

those on the railway stations, until one considers that the latter are seen by passengers who are in many instances glad of anything to relieve the tedium of their waiting, when it is at once plain that there is a considerable difference in their values. These cases are indeed but hoardings on a smaller scale, and as such do not constitute good mediums.

Directories.

Many photographers, doubtless as a result of the eloquence of the canvassers employed, advertise in directories. There are directories and directories. In some towns and suburbs there are excellent little directories. Kelly's Buff Books may be cited as an instance, in which there is a great amount of local information, and this, added to their low price of one shilling or thereabouts, is sufficient to assure them sufficient local circulation to give them a certain value to the photographers in whose towns they are issued. On the other hand, there are the bulky directories, national in their scope and proportionately costly in price, which a moment's reasoning should convince the photographer are not worth, to him, the three or four shillings which he is asked to pay for the insertion of his name in bold type. This brings us to the important point that in

Giving Out Advertising.

the photographer should not allow the persuasions of the canvassers to carry much weight; he should invariably be guided solely by his own knowledge of local conditions. If there are three newspapers in one town, he will know from his own observation which has the largest circulation, and which, other things being equal, is therefore the most valuable. He will know, too, that the evening papers are frequently bought merely for the sporting news they contain, and that they are not taken into the household to the extent that are the morning and the weekly papers. In fact, he cannot exercise too much care in the choice of his mediums: fortunes have been made by advertising, and so also have they been lost, but it has always been because the money has been injudiciously laid out—the fault of the advertiser, not that of advertising.

Sending Circulars.

Many photographers who do not advertise in any other way are believers in the distribution of circulars, but unless in exceptional instances, where there may be local conditions not prevailing elsewhere, we do not consider circulars of much value. If distributed from door to door, they take their chance with the almost innumerable calendars and other matter issued by the patent medicine people and the highly-coloured circulars of the local draper announcing "gigantic clearance sales," the numbers thus distributed being now so great that many householders have come to regard them as an unmitigated nuisance. Not much better is the halfpenny postal wrapper, and by the time we reach the ordinary penny stamped envelope the cost of sending any number begins to be prohibitive. Instead of sending so many hundreds of circulars addressed at random, it were better to write letters with a definite object in view. If, for instance, the announcements of births in the local newspapers be filed, about two or three months later a letter might be sent suggesting that Mrs. So-and-so may possibly be requiring some photographs, and incidentally mentioning that "Our Mr. Hypo has devoted especial attention to the portraiture of children, one of the most difficult branches of photography, but one which at the hands of the skilled operator gives its most charming effects." The addresses of the secretaries of all the local organisations should be kept, that directly a show or meeting of any sort is announced a list of the exhibitors or people interested may be obtained and an appropriate letter sent. The manufacturers in the neighbourhood should be written to, pointing out that nowadays all printed catalogues are almost necessities, and that half-

tone blocks from direct photographs of the objects, afford superior illustrations to the woodcuts which they may possibly still be using. The same point may be used in a slightly modified form in approaching many shopkeepers.

The Appearance of the Studio.

The first "move" having been made in any of the ways already mentioned, and the object of bringing the sitter to the studio having been achieved, we turn to other considerations. The most important, perhaps, is that absolute cleanliness and orderliness be observed in both reception-room and studio—yet how often are both lacking, and generally the photographer who is least able to spend money on what he deems would be improvements, is the worst offender, and to remedy the most obvious defects would cost—nothing. It is the careful attention to the little things that leads to success. A lately deceased magnate in the world of West African mining finance told the writer how that when he first came to London it was as a photographer's assistant in search of a job in any capacity. He went to one of the leading West End studios. "No," said one of the partners, "we have no vacancy." The youth stepped to a window, and, moving a curtain slightly, remarked that it seemed a pity to allow the strong sunlight to pour in on the costly plush, on which it had been shining. The partner was so impressed by the careful observation which the remark denoted, that he there and then engaged the youth, whose successful after-career was marked by, and can largely be attributed to, the same attention to details. Every photographer can with a little care see that there is no room for fault to be found in this respect, but the question of taste in the appointments is a little more difficult. Not everyone can make his studios so attractive as to render them the rendezvous of fashion in his town as has the American photographer, Mr. J. C. Strauss, in St. Louis, but he should at least have his surroundings in what is generally recognised as being in good taste. Frequently, though, one sees a reception-room furnished with ugly furniture and the walls of many-coloured paper almost covered with all sorts and conditions of photographs, instead of a subdued self-coloured paper on which are displayed a few well-framed specimens of the very best photographs the proprietor has produced. The choice of

The Receptionist.

is another "move." A photographic humorist has written, "Show me a photographer's receptionist and I will show you his bank-book," and the remark contains much truth. An agreeable manner and the possession of a little tact will frequently mean that a sitting will yield an order double or treble that which it was originally the intention to have given, and thus it is that we contend that the engagement of a good receptionist comes within the definition of advertising, with which we started, "Every move that has for its ultimate aim the sale of anything."

The Photographer's Stationery.

is a means of advertising which is often misused, generally through trying to advertise too much and thus defeating its own ends. Many photographers seem to aim at the same effect on their stationery as do the dealers and manufacturers, forgetting that the latter necessarily appeal to varied interests, whereas the plain statement that the letter is sent from a certain studio should be sufficient for the photographer. Instead of which, one sees a lengthy list of processes in which prints and enlargements are made, and information that the latter may be obtained finished in oils, water colours, or monochrome—the last word reminding one of "that blessed word Mesopotamia," and probably conveying about as much meaning to most of the recipients. Sometimes there is a crude woodcut—very wooden at that, too—of a design which ill befits an "artist" in photography writing to his patron. Again, the use of one printed form for both letters and bills misleads some.

To use a sheet of note paper for a bill looks professional—doctors and solicitors both do it—but to use what is, by its cash columns, obviously a bill heading as a letter is bad form. Unless executed in very good style a design of any kind is much better avoided; the name of the photographer, with the single word "photographer" below it in the left-hand corner, and in the right hand, the address, if well printed, or better still, embossed, in a quiet colour on the best paper one can afford, will be quite sufficient.

In Conclusion.

Lastly, the work turned out is the last "move." It is the final advertisement and the most lasting. If it be not good, all

the other advertising will have been in vain. Badly washed prints will tell their own story within a few weeks, and so will cheap mounts when the chemical impurities therein shall have had time to work through the mountant. Such sophistries as sending out bromides as "platinos" may pass muster for a time, but in business, apart from any ethical or religious considerations, honesty is the best policy. The photographer who judiciously advertises to attract attention to his work, will find that if the latter be good he will keep on getting more to do. Only—he must keep to the one standard. The work must be good.

W. J. CASEY.

A PICTURE SCRAP-BOOK.

By an Occasional Correspondent.

A FEW years ago I picked up a copy of an American photographic magazine, and as the frontispiece I saw a copy of a photograph by Hollinger. It was a fine picture of a white-haired, handsome man, just the kind of sitter who makes a good subject, and one who had been fortunate in choosing a photographer who appreciated the possibilities in his subject, and made the most of them. But it was not merely as a successful piece of work that it interested me. I was sure I had seen the original, or his portrait, before, and I cudgelled my brains to remember where. The idea bothered me for days, when suddenly I had an inspiration. I rushed into Cook's, laid eight and fourpence on the counter, and asked for a two-dollar United States bill. On the back were two engraved portraits, one of them being Morse, the man famous in the early days of electrical research. He was a fine old man, with a wealth of snowy hair. At once I saw that I had found what I was searching for. Hollinger had got his idea from American paper money.

An Observation.

This Hollinger is an unusually successful American portraitist; a man who went from a small country town to New York and at once took a place in the metropolis somewhat similar to that now held by H. Walter Barnett in London. He became famous among American photographers as the man who obtained record prices, and as the man who did not pose his subjects. That advice of his, "Don't pose," was a rock of stumbling to his fellow workers, and many of them doubtless have not grasped it to this day. They thought he meant, "Let the sitter pose anyhow, and just fire away"; but when they tried that, they found the result to be disaster rather than record prices. Hollinger simply did not pose to any preconceived or stereotyped rules of the trade, and he strove after naturalness in his sitters as the first essential. His secret, of which he made no secret, was close study and observation. His finding inspiration from an old engraved portrait is typical of him. Week after week when he reached New York he would go to the leading art museum and study the pictures. Never an illustrated paper came his way but he absorbed some hint from its pages—if the hint were there. The modestest of showcases attracted his attention, and he was never tired of seeing even the most mediocre of work. He absorbed the good, rejected the bad, and got such a grasp of his subject that he chose the best pose as by instinct, and without conscious effort.

Keeping Ideas.

Every self-respecting man reads one or more papers, and sees a number of illustrated magazines. The trouble with ephemeral literature is its great profusion. To turn over four or five illustrated papers in the course of half-an-hour is simply to

pleasantly pass that time away. The pictures are lazily glanced at, and forgotten. If a man has the questionable habit of "keeping papers for binding," they are kept until the auspicious day in the lumber room. Moving day usually comes first, and the bundles of papers strike despair in the owner. "Carry all this dead weight away? No fear!" he cries; and he is secretly relieved at leaving them to worry the next tenant.

The proper place for ninety-five per cent. of current literature is the waste-paper basket. Papers are issued week by week for the needs of that week; not for posterity. But most magazines, if they are worth anything at all, contain some sketch or photograph which furnishes a hint or an idea. If so, cut it out and save it, while the rest of the paper goes to fire-lighting. Such a selected note may be of use at some future date. If left in the magazine, and the magazine in the lumber room, it will never be seen again.

How to File Cuttings.

The mere act of examining a picture which strikes the eye as one worth saving is in itself a help, for the picture receives a close inspection instead of a mere cursory glance. But the pictures are kept for future help and use. How may they best be filed so as to be at hand when required? There is no way to beat the old scrap-book idea. Keep a few envelopes for the different classes of pictures—men, women, children, groups, etc. At occasional intervals go through the envelopes, discard those pictures which on second inspection appear too commonplace, and mount the others in a book. Dozens of photographers have worried over the problem of how best to do justice to a bridal dress with its emphatic train. I know a photographer who has half a hundred such pictures; not only photographs, but also sketches and engravings. An hour spent with such a collection would be a privilege to many workers.

The Value of Engravings.

A common mistake made by the photographer in search of ideas is to confine his search to the photographic field. Photographs show a wider range of pose and arrangement to-day than ever they did, but there is still room for improvement, and much may be learnt in this direction by studying the work of pen or brush artists. Photography depends so much on its technical end that some photographers make this the leading part of their knowledge. The training of the artist brings him into closer touch with such questions as arrangement of line, or composition of a picture, and this phase of his work is emphasised when he comes to block out a composition which may take hours, or weeks, of unremitting care in its realisation. Nowhere is this more plainly seen than in the difficult problem of groups. With a group of fifty people the photographer is happy. One row sitting on the ground, one on chairs, one standing, and perhaps a fourth row standing out a form. But when it is a question of three or four people, the

photographer often has an anxious time, and not infrequently feels very dissatisfied with his results. A picture in which a very few persons are pleasingly grouped is well worth study by a photographer.

Old Masters.

From time to time we hear about old masters, and perhaps some people are a little tired of them. And too much reliance may be placed on them. The photographer may get a hint of attitude or a suggestion of arrangement as well from a sketch in a penny paper as from a guinea photogravure. But it is well always to study the best, without necessarily closely imitating it. When a picture has been hung on a wall for three hundred years, a photograph of it is scarcely the thing to be studied as a masterpiece of photography. A fashion of a dead black background has nothing to do with a guarantee of art. Old masters may be studied, however, from the vital viewpoint of likeness—a likeness that goes beneath mere skin-

texture and gives us the character of the man. It is impossible to look at many of the world's great paintings without reading the characters of the men portrayed—and, indirectly, of the artists.

Expression and Anatomy.

Among the thousand and one pictures in magazines we get hints of poses and drapery. "Pretty pictures" are popular, and the photographer who makes his feminine sitters look graceful and dainty will share the popularity. In looking at the old masters—most of which are representations of men—we find that the expression is more than the anatomy; that the man is revealed, not the mask. With our modern ideas of retouching we tend to destroy both mask and man. The keeping and study of a picture scrap-book is a very useful item in a photographic education; but the greatest factor of all—the study of the human face itself—must never be neglected. It should be an ineradicable habit.

THE WEEK IN HISTORY.

The Gum Bichromate Patent.

IN "The Week in History" for March 24 I referred to Pouncy and his invention of the gum process, for which process he took out a Provisional Specification on April 10, 1858. From the brief preamble to the technical description of his method it would seem as though Pouncy imagined the invention of a photographic image in pigment *via* bichromate and a colloid body like gum to be original with him. "Heretofore," he writes, "in producing photographic pictures on paper and other surfaces, the surface has usually been prepared with substances which, when acted upon by light in the process of producing the picture, are chemically acted on so as to produce, either immediately or when other substances are afterwards applied to the surface, the colouring matter or substance in which the picture is formed." But the credit of photographic printing in permanent pigments belongs to Poitevin if any one man is to be named for that distinction. Poitevin's work, which forms the basis, not only of pigment printing, but of the important colotype process, commenced in the late forties. In 1855 an English patent was granted to him which embodies the principle of colotype, and in the same year he produced crude pigment prints by the use of gum and albumen and a bichromate. Pouncy thus developed and perfected the idea of the French inventor.

Gum-Bichromate as a Trade Demonstration at the R.P.S. Forty-Seven Years Ago.

In 1858 Mr. Pouncy stirred the (then) Photographic Society of London to its depths with his gum-bichromate process. At a December meeting in that year he was introduced as about to read a paper, but that he did not do. The evening witnessed a spirited attack upon him by Mr. Malone, who complained of the Society being used for purposes of trade, and further poured forth the vials of his wrath on "carbon"—as Pouncy called his process—in comparison with silver. The point of his brilliant argument—which I recall now as delivered with great animation—was distinctly blunted by the fact that between two prints shown by Mr. Pouncy, one silver, and the other authenticated as "carbon," Mr. Malone was not able to distinguish. At

the subsequent meeting Mr. Pouncy made known the details which he had previously withheld, and there was once more peace upon the waters.

Whatever publicity the Pouncy process obtained at that time—it was very considerable—it availed it little. For transfer carbon, then in embryo, was soon afterwards developed by Swan, and no more was heard of gum bichromate until the Frenchmen rediscovered it in 1894.

The Aniline Process.

Probably nine out of ten photographers have never heard of, and certainly never worked, the remarkably simple process which is exactly forty years old on Tuesday in next week. The aniline process was made known by its author, Mr. W. Willis, in a paper to the Photographic Society on April 11, 1865. It is a simple and effective application of the sensitiveness of bichromate to light and the well-known oxidation of aniline by bichromate into the dark dyes which formed the starting-point of the aniline-colour industry. As Mr. Willis describes it, the sensitising liquid consists of a solution of the bichromate of potash or ammonia, containing a small quantity of sulphuric or phosphoric acid. This liquid is applied to paper either by sponging or by floating. When dry the paper is exposed to light under a positive photograph or a drawing after which it is placed in an atmosphere charged with the vapour of aniline. Finally the print is washed in either plain water, or first in weakly acidulated water, and subsequently in plain water. The reader will see that in this process the image is formed, not from the substance which is formed, but from that which is left unchanged; it is the residual bichromate which produces the aniline colour when the print is exposed to its gaseous developer. Hence the process is chiefly useful for the copying of line plans and tracings which it is very desirable to reproduce in dark lines on a white ground. It was very largely employed for this purpose in Germany in engineering works for the multiplication of shop-drawings, for it is extremely cheap, extremely rapid, and the copies, although they are in dyes, are perfectly permanent.

HISTORICUS.

MEQUIN.—The developer which has obtained a universal reputation under the name "M.Q." (metol-quinol) is probably well known, from actual acquaintance with its properties, to every reader of these pages. This product was brought upon the market in 1894 by Messrs. John J. Griffin and Sons, primarily as the developer for Velox paper, and has been sold for some years past under its name, "M.Q." As this title cannot be registered, and as, therefore, the distinguishing mark of an excellent product can be used by other

makers, Messrs. Griffin have now taken the step of protecting themselves by registering the word "Mequin," to identify their manufacture. "M.Q.," as made by Messrs. Griffin, should be as acceptable to photographers by any other name, but the new synonym impresses us as extremely felicitous, and we trust that the qualities of excellence and uniformity which it has been our experience to observe in the developer hitherto will be appreciated no less now that "M.Q." changes its name to "Mequin."

DR. MIETHE'S COLOUR PHOTOGRAPHY IN LONDON.

ONE outstanding attraction at the Photographic Trade Exhibition, which opens to-day at the Portman Rooms, Baker Street, London, W., is the projection of three-colour transparencies by the apparatus devised by Dr. Miethe and constructed for him by the well-known firm of C. P. Goerz. Some time ago exhibitions of the many trichromatic portraits taken by Dr. Miethe himself were regularly held in the Urania Theatre, Berlin, and now, after having twice crossed the Atlantic and having been a notable object of interest in the photographic section of the St. Louis Exhibition, Dr. Miethe's colour photography will be offered to the public view for the first time in England while the Portman Rooms are devoted to the photographic trade—viz., from April 7 to 14. The apparatus has a personal interest for us, as we chanced to be present when the first

mon to all three systems, however, is the cooling tank, which is designed more to protect the transparencies than the condensers from the heat. The lamps are hand-fed, and the current can be varied between 15 and 35 amperes, according to the size of the disc. The condensers are of the triple form, with a meniscus with its concave side to the light, and then two plano-convex lenses, with their convex sides towards one another, and between these two lenses is placed the water tank, which is filled with distilled water containing a little carbolic acid, and has an internal separation of about 6 cm.

The lenses and colour filters are arranged on three parallel optical benches, a design which permits of very exact movement along the optical axes. Special fittings are arranged for coarse and fine focusing, for raising and lowering, and a to-and-fro movement.

Dr. Miethe's Apparatus for Three-colour Projection. Photograph by C. P. Goerz.

working model was brought to Dr. Miethe's laboratory, and we heard his playful comment—"Ein schönes Thier!"—as he handled the roughly-constructed instrument. The projection lantern, as Messrs. Goerz have made it, is an instrument of precision. The following outline of its construction will explain how it differs from other projectors of trichromatic transparencies, and we give it with the recommendation to our readers to overlook neither the apparatus nor the marvellously beautiful colour photography which it displays when paying their visit to the Portman Rooms.

The apparatus, as devised by Dr. Miethe, was constructed by C. P. Goerz, of Berlin-Friedenau, and enables the images to be adjusted and superimposed before being thrown on the screen. It practically consists of three projection lanterns placed side by side, each having its own arc lamp, condenser, and projection lens. Com-

The filters are stained gelatine films cemented between plate glass, and fit somewhat like a cap on the lens hoods. Dr. Miethe claims that by this arrangement and suitable choice of the dyes the filters have a very long life, as in this position they are least exposed to the intense light: and it has been proved that they will stand for at least one hundred working hours.

The lamps, as already stated, are hand fed with inclined carbons, and so arranged that the crater may be moved vertically and horizontally. The resistances are capable of regulation, so that the current may be kept within the specified limits by turning a lever, and the constancy of the current is tested by three ammeters, from the readings of which the length of the arc is from time to time adjusted.

As regards the consumption of current, 13 to 15 amperes for each lamp are enough to illuminate brilliantly a screen from 7½ to 8 sq. ft.

with vivid colour rendering. For larger discs the current must be increased, and with 30 amperes a surface of about 15 sq. ft. is sufficient without any appreciable loss of light.

As the effect of the projection in colours depends to a very great extent on the regularity of the burning of the lamp, it is advisable to use nothing but the best carbons, and Dr. Miethe states that he has found the cored searchlight carbons marked "S. A.," made by Siemens and Halske, the best, and he uses cored carbons both for the negative and positive poles, and thus gets a quieter burning arc. The arc itself should be kept rather short than long, and the cable carrying the current should be so arranged that the arc is disturbed as little as possible by the electro-magnetic action of the current, and for the same reason the lamps are separated by sheet-iron.

Peculiar to this large projection apparatus of Miethe's is the transparency carrier. This is constructed of sheet aluminium, and when the positives have been once adjusted they always remain in the required position. The sheet of aluminium is cut with three square apertures, slightly less than the positives, and by the aid of spring clips, the positives, when they have been cut apart, can be fastened in this frame.

Accurate superposition of the three images may be obtained in one of two ways. The centre picture may be fixed in the apparatus and the two side ones shifted till they absolutely coincide, and then they may be clamped, or a special adjusting apparatus may be fitted, which can be used by day or by lamp light and without using the projection lantern. This apparatus consists of two microscopes, a slit, and a cross wire, which is accurately adjusted on a particular spot or subject in the positive, and then the same operation gone through with the other positives, though in this case the microscopes are kept fixed, and the positives moved. When the cross wire coincides with the same point as in the first positive, the positives are fixed in position in the frame, which is then ready to drop into the lantern, and the images will at once coincide on the screen, if the lanterns have been previously adjusted. Dr. Miethe states that from forty to fifty sets of positives can be thus adjusted in a morning.

To adjust the lanterns, an enlarged cross-line screen negative is used, two lanterns are lit up, and the images made to coincide, and then the third adjusted in the same way. Although extremely small differences may be seen they are of no moment.

Dr. Miethe originally used cells with liquid filters, but now he uses stained gelatine, and it is interesting to note that he states that precisely the same filters may be used for projection as were used for taking the negatives, though it is an advantage to use lighter ones, particularly in the case of the blue. Mr. F. E. Ives always contended and used, for projection, filters which practically allowed but a very narrow spectrum band to pass whereas according to this statement of Miethe's and a spectroscopic examination of a set of his taking-filters, each passes a broad, but not over-lapping spectrum band.

THE proposed amalgamation of the Society of Arts and the London Institution is discussed at considerable length in the current issue of the Society of Arts "Journal" in the form of the report drawn up by the managers of the two institutions. It is shown that both bodies are in a prosperous state, and that the fusion of their interests and the establishment of a compound body in a building in the West End should add to the facilities which are now separately enjoyed by the two bodies for the prosecution of their labours. It is hoped that the new institution will permit of the promotion of scientific research, once a main object of the London Institution, but one which it has lately been compelled to abandon.

Photo-Mechanical Notes.

Enlarged Half-tone Work.

WE observe on the hoardings at present two very large full-length portraits in costume of Mr. Fred Terry and Miss Julia Neilson, as characters in "The Scarlet Pimpernel," and on examination these prove to be half-tones, as does also the smaller poster for the same play, a flower containing Miss Neilson's portrait. These posters are by Messrs. Allen, the well-known theatrical poster publishers. At Christmas, conspicuous everywhere was a huge Christmas pudding with some children around it, also half-tone, worked with colours. Messrs. Meisenbach, Ltd., have lately circularised the lithographic printers, offering to supply at low prices half-tone lithographic transfers up to 60 in. by 40 in. from flat photographs of any size supplied, or to specially make photographs from living models, and from these the transfers. All this shows the steady trend of photo-mechanical reproduction towards conquering every branch of reproduction work.

Enclosed Arcs and Bluish Originals.

In making negatives of bluish wash drawings with the enclosed arc-lamps which are now coming into use, it is often found that the reproduction is very flat as compared with the original. This is probably due to the fact that the light blues reflect nearly as much ultra-violet as the whites, and the result is a loss of tone. The exposures with this kind of original are usually so short that it is no great sacrifice to cut out some of the ultra-violet—indeed, it is essential, if the etcher is not to be given much work on the metal in correcting the defective tone rendering.

A filter should be used of quinine sulphate, 1 part; water, 100 parts, solution being effected by the addition of a drop or two of sulphuric acid, or a filter of bichromate of potassium, 1 part, in water, 10,000 parts, will also cut out the ultra-violet. These solutions are used in a cell of 10 millimetres thickness. If the bichromate filter is made stronger, it begins to cut out the violet and the blue, and exposures become so long as to make the use of wet collodion impracticable. Either of the above weak filters may, however, be used with ordinary wet plates without very seriously prolonging exposure.

A Process Copy-holder.

AN accessory of some considerable value to the process worker is a copy-holder which we recently saw in use at the L.C.C. School of Photo-Engraving, Bolt Court, Fleet Street, London. It consists very

simply of a frame like an ordinary deep printing-frame, provided with two hangers for attachment to the easel, and is made without projections at the back, so that if the easel is correctly at right angles to the axis of the lens, the glazed front of the holder and also the

copy which is pressed against it will likewise be properly placed. The lack of the holder is inserted if the copy is an unmounted drawing or print, but is dispensed with if a book or thicker object is to be pressed flat against the plate-glass front of the holder. As permitting almost any form of original to be held flat, the accessory is certainly an aid to the photo-engraver, and we understand that it is made in 20 x 16 size for 15s. 6d. by the Camera Construction Co., of Hackney, N.E.

PHOTO-MECHANICAL PATENTS.

Application for Patent.

HALF-TONE SCREENS.—No. 6,296. "Method of producing half-tone photographic screens." Theodor Dittmann, 40, Chancery Lane, London.

Exhibitions.

NOTTINGHAM.

THIS exhibition was opened on Wednesday, April 5, by Sir Henry Cotton, K.C.S.I. The entries are well up to the average, the open section containing many of the season's best pictures, the landscape and portraiture classes being particularly strong. The members' classes were never so well filled, nor has the work attained so high a standard as upon this occasion—some of the work might with advantage have been entered for the open classes. The club has adopted a most commendable arrangement in having the awards presented at the opening ceremony, the judging, we understand, being done early enough to allow of this.

The evening programmes include lectures by Sir Henry Cotton upon the great earthquake in the West Indies, and upon Holland by the President of the Club, Mr. Arthur Marshall.

The Club is to be congratulated upon a most successful exhibition, and upon the vitality and enthusiasm which exist amongst its members.

The judges, Messrs. J. T. Ashby and C. Barrow Keene, made the following awards:—

OPEN CLASSES.

Class A—Landscape, Seascape, and River Scenery: Bronze plaques, Chas. E. Walmsley, Arthur Marshall; hon. mentions, Arthur Black, Hugh G. Paterson.

Class B—Portraiture, Figure Studies, Animals, and Still Life: First bronze plaque, A. E. Coleman; second bronze plaque, Hugh G. Paterson; third bronze plaque, John Spark; first hon. mention, D. W. Kyle; second hon. mention, Chas. E. Walmsley.

Class C—Architecture and any subject other than Classes A and B: First bronze plaque, W. A. Clark; second bronze plaque, Arthur Marshall; hon. mentions, Thos. Wright, Noel Blagg, Wm. Mosley.

Class D—Lantern Slides (set of four, any subject): First bronze plaque, Rev. Henry W. Dick; second bronze plaque, Hugh G. Paterson.

MEMBERS' CLASSES.

Class E—Landscape, Seascape, and River Scenery: First bronze plaque, R. R. Enfield; second bronze plaque, Thos. Wright; hon. mentions, S. D. Middleton, E. H. Atkin.

Class F—Portraiture, Figure Studies, Animals, and Still Life: First bronze plaque (withheld); second bronze plaque, Thos. Wright; hon. mentions, F. H. Radford, Noel Blagg.

Class G—Architecture, and any other subject than above: First bronze plaque (withheld); second bronze plaque, E. H. Atkin; hon. mentions, Thos. Wright, S. D. Middleton.

Class H—Lantern Slides (sets of four, any subject): Bronze plaque, Arthur Black; hon. mention, Thos. Wright.

Class J Novices' Class (for members who have never received

an award of any kind for photography): Bronze medals, W. A. Appleton, W. H. Kirkland; hon. mentions, D. Gillespie, John Gale, Wm. S. Ellis.

President's Special Award—The special award of £2 2s. offered by the President of the Club for the best print in gum-bichromate, entered in the Members' Classes, has been awarded to Mr. Alec Hartley.

PHOTOGRAPHIC SOCIETY OF IRELAND.

THE annual exhibition of this Society was opened at the Leinster Lecture Hall, Dublin, on Monday, and will continue open until the 15th inst.

The following is the list of awards:—

MEMBERS' CLASSES.

Class 1—Landscape, etc.: Silver, R. Benson; bronze, Rev. R. E. Vernon Hanson; hon. mention, Mrs. F. Perry, T. H. Mason.

Class 2—Portraits: Silver, Mrs. Mahoney; bronze, A. Ponton; hon. mention, Mrs. F. Perry, T. A. Hackett.

Class 3—Architecture: Silver, J. B. Anderson; bronze, H. Pollock. Class 4: Bronze, Mrs. F. Perry, Mrs. Mahoney; hon. mention, J. B. Anderson.

Class 5: Silver, H. Pollock; bronze, H. Goodwillie; hon. mention, Basil Thompson.

Class 7: Bronze, A. Ponton; hon. mention, S. J. Harrison.

Class 8: Bronze, W. C. Wilson; Werner special award: Mrs. Mahoney.

OPEN CLASSES.

Class 9: Gold, Arthur Marshall; silver, A. E. Coleman; bronze, J. M. Whitehead.

Class 10: Silver, J. B. Doran; bronze, J. M. Keogh.

Class 11: Silver, Rev. H. Dick; bronze, F. G. Tryhorn.

A feature of the exhibition is the loan collection of pictures by the members of the Salon Club of America.

CHISWICK.

CHISWICK CAMERA CLUB's ninth annual exhibition, which was held in the Chiswick Town Hall, on Thursday, Friday, and Saturday last week, and Monday of this week, has gradually increased in magnitude year by year, and this year there has been added an apparatus section to it. In the pictorial section the judges were Rev. F. C. Lambert, M.A., and Mr. S. J. Beckett. In Class A (open) the silver medal was awarded to H. Gordon Stollard, for "A Sussex Lane"; the second medal (bronze) went to H. O. Bannister, for "Finishing Touches"; and the third (bronze) to J. B. Portway, for "Going to the Fold." In Class B (affiliated societies), for sets of four frames by four members of club, the medals went to the Hastings and St. Leonards Photographic Society for frames "A Country Girl," by Harry Cross; "Finishing Touches," by H. O. Bannister; "A Study of Old Age," by John Smith; and "November," by Fred. Judge. In Class C (members) (Landscape, River Scenery, and Marine), "The curfew tolls the knell of parting day," by W. E. Walker, gained the silver medal; the bronze medals went to W. E. Walker, for "The Harbour Sunset," E. R. H. Wingfield, for "A Corner of Hampstead," and H. Hucklebridge, for "St. Paul's." In Classes D, E, and F, the entries were very sparse, and there were no awards in them. In Class G (open), (Lantern Slides), H. Wormleighton's set of slides (various) gained the bronze medal. In Class H (members) (Lantern Slides), J. Woodger's set (various) gained the bronze medal. The apparatus section, which is entirely under the control of the Exhibition Committee, had selections of the latest apparatus of the following manufacturers: Messrs. Houghtons, Ltd., Kodak, Ltd., R. and J. Beck, Ltd., W. Butcher and Sons, W. Watson and Sons, and the Wizard Camera Co.; also specimens and samples of "Tabloid" specialities, Wellington and Ward's papers, and the Rotary Co.'s specialities.

FOURTH PHOTOGRAPHIC TRADE AND PICTORIAL EXHIBITION.

THE photographic exhibition which opens at the Portman Rooms (Baker Street, W.) to-day promises to be one of the most interesting photographic events of the season. It is the fourth of a series of exhibitions held primarily in the interests of the trade, but in the present case the addition of pictorial exhibits by professional and amateur camera users has given the event a much wider scope and significance. It is the hope of the management that the general public will be attracted to the show in greater numbers than on previous occasions, and this will add a more direct interest and value to the affair from the trader's point of view. That the exhibition is a thoroughly representative one will be gathered from the accompanying list of exhibitors as supplied to us by the management at the time of going to press:—Elliott and Sons, Ltd.; Johnson and Sons; J. Ashford; C. P. Goerz; J. E. Lockyer; Adhesive Dry Mounting Co., Ltd.; Benetfink and Co.; A. and M. Zimmermann; Rajar Ltd.; Houghtons, Ltd.; R. W. Thomas and Co., Ltd.; D. Allan; Romanet and Guilbert; Dawbarn and Ward; C. Tyler and England Bros., Ltd.; Carl Zeiss; Butcher and Sons; Busch Camera

means of an elaborate specially designed and constructed piece of apparatus of C. P. Goerz, which we describe on another page. The latest in animated photography is also to be a feature of the entertainments.

The pictorial section is comprised of competitive exhibits by many of the best known workers in the United Kingdom, together with a loan collection contributed by eminent professional and amateur pictorialists. This section is under the management of Mr. Walter Selfe, the well-known honorary secretary of the Hackney Photographic Society. Six silver and six bronze plaques, and a gold medal for the best picture in the exhibition are to be awarded, the judge being Henry W. Bennett, Esq., F.R.P.S.

In every other respect the exhibition is being organised upon most popular and attractive lines. A good smoking and refreshment saloon is provided, and there is a capital orchestra. The exhibition remains open until Saturday, April 15, from 12 noon to 10 p.m. daily. It is well worth a visit, and being within three minutes' walk of Baker Street station, on the Metropolitan Railway, is very convenient and accessible. The admission fee, 1s., covers everything, there being no extras.

1. The Secretary's Office.
- 2 and 3. Jas. Walker & Co.
7. Moll & Jonas.

72. Daniel Judson & Son.

Co.; Wizard Camera Co.; Burroughs Wellcome and Co.; O. Sichel and Co.; A. C. Jackson; Paget Prize Plate Co., Ltd.; C. Zimmermann and Co.; Moll and Jonas; D. Judson and Co.; A. Alston; J. Wrench and Son; Rogers and Webster; Rotary Photo Co.; Penrose and Co.; Lancaster and Son; Leto Photo Materials Co.; Illingworth and Co.; Metatype Co.; Chas. Harrison; Bayer Co., Ltd.; Gaumont and Co.; S. Albu and Sons; H. Edmund and Co.; Service Photo Society; Rosenberg and Co.

We understand that every effort is being made by the participants to bring together a thoroughly up-to-date array of novelties and accessories. The rooms themselves are admirably adapted for the effective display of goods of this description. The entertainment department is characterised by great variety, all the latest novelties in lantern and cinematograph work having been arranged. Dr. Miethe's colour slides from the St. Louis Exhibition should prove specially interesting. These are being shown upon the screen by

SHOTS'S EXHIBITION.

THE Shots's Camera Club is of comparatively recent formation, but that the members have a large fund of enthusiasm is evident by the exhibition held at the end of last week. In the open class J. C. Robertson, Brechin, carried off premier honours—the silver plaque—with his picture "The Picture Book"; bronze plaques were awarded to Wm. Clayden, Plymouth, "Tugging Home," and Fred Judge, Hastings, "November," while diplomas were gained by E. Seymour, Watford, "Flower Study." Vanessa C. Baird, Broughty Ferry, "Loch Vennacher," and R. Forbes, Edinburgh, "Waiting."

In the federation class the silver plaque was gained by G. L. A. Blair, Paisley, with "While London Sleeps." J. C. Robertson, Brechin, gains the bronze plaque with "A Study in Architecture." Diplomas were awarded to Mrs. V. C. Baird, Broughty Ferry, "Gipsy Life," and A. H. Allan, Edinburgh, "Figure Study."

In the members' class the bronze plaque awarded by the president

(A. W. Hill) is gained by J. Twaddle, secretary, with "Corn," he also gains a diploma, as also do Alex. Smith and S. Forsyth.

Probably the feature of the exhibition from a photographic point of view is the 27 prints exhibited by A. W. Hill, president of the society. These prints, as might be expected from the well-known proclivities of the author, are all gum-bi prints, and certainly they show a wide range of treatment and dexterity in the use of his chosen medium.

Mr. J. W. Eadie, Vice-President of the Scottish Federation, officiated as judge.

THORNTON HEATH.

THE annual exhibition of this society was held on Tuesday evening on last week, at East Surrey Hall, when 136 pictures were shown. The judging was done by Mr. J. T. Ashby, F.R.P.S., in whose opinion the best picture in the show was one contributed by Mr. W. H. Rogers. The awards were distributed in the evening by Mr. W. H. Smith, president of the Croydon Camera Club, and were as follows:—Class A., Landscapes, etc.: 1st "A June Morning," by G. L'Epine Smith; 2nd "Wotton Woods," by Fred Stokes. Class B., Architecture, Portraiture, etc.: 1st "An Interior," by W. Wood; 2nd "Innocence," by E. J. Smith. Class C., Any Subject: 1st "Through the Grey Mist," by J. H. Robertson. Class D., Lantern Slides: 1st Mrs. Edwards; 2nd W. Wood. Class E., Open: 1st "Towards the Close of Day," by W. H. Rogers; 2nd "A Spring Morning," by G. W. Jenkins.

FORTHCOMING EXHIBITIONS.

April.—International Exhibition, Genoa. Sec. Gen., Piazza Fontane Marose 18, Genoa.

April 3-15.—Photographic Society of Ireland. Hon. Secretary, R. Benson, 35, Molesworth Street, Dublin.

April 5-8.—Nottingham Camera Club. Hon. Secretary, S. W. B. Vines, 102, Woodborough Road, Nottingham.

April 7-15.—Photographic Trade Exhibition, Portman Rooms, Baker Street, London, W. Manager Pictorial Section, W. Selfe, 70, Paragon Road, Hackney, London, N.E.

April 7-May 8.—International Artistic Exhibition, Berlin. Director, Herr Franz Goerke, Maassenstrasse 32, Berlin, W.

April 24-29.—Redcar and Coatham Literary Institute Photographic Society. Secretary, W. Hildrith, 42, Newwomen Street, Redcar, Yorks.

April 27-29.—Southend-on-Sea Photographic Society. Hon. Sec., J. Archer, 24, Ashburnham Road, Southend-on-Sea.

April 28-29.—Watford Photographic Society. Hon. Secretary, C. J. Trevarthen Ashcroft, Bushey Hall Road, Watford.

May 1-31.—International Exhibition of Photographic Picture Postcards, concurrently with the 10th Salon. M. le Secrétaire-Général du Photo Club de Paris, 44, Rue des Mathurins, Paris

May 9-10.—Ballarat Camera Club. Hon. Secretary, G. Montgomery, 201, Sturt Street, Ballarat.

May 10 to June 19.—Salon of the Photo Club de Paris. Entries close March 1, and pictures must arrive by April 10. Secretary, Paul Bourgeois, 44, Rue des Mathurins, Paris.

June.—Northern Photographic Exhibition. Secretary, F. G. Issot, 62, Compton Road, Harehills, Leeds.

November 21-25.—Southampton Camera Club. Hon. Secretary, S. G. Kimber, Oakdene, Highfield, Southampton.

December 1-6.—Hove Camera Club. Hon. Secretary, A. R. Sargeant, 55, The Drive, Hove.

December 12-20.—Southsea Photographic Society. Hon. Secretary, F. J. Lawton, 5, Pembroke Road, Portsmouth.

FORTHCOMING COMPETITION.

September.—Kodak. £400 in prizes for results on Kodak products. Kodak Ltd., 57-61, Clerkenwell Road, London, E.C.

Patent News.

Process patents—applications and specifications—are treated in "Photo-Mechanical Notes."

The following applications for patents were made between March 20 and 25, 1905:—

DARK SLIDES.—No. 5,822. "Improvements in envelopes and dark slides for plates and flat films, and in camera backs and adapters receiving them." Max Staehler, 29, Margaret Street, Regent Street, London (Firm of Carl Zeiss, Germany).

RETOUCHING APPARATUS.—No. 5,840. "New or improved apparatus for use in photographic printing and retouching." Thomas Clegg, 38, Chancery Lane, London.

MARKING PLATES.—No. 5,852. "Improvements in and relating to means for marking photographic plates." William Frederic Butcher, 322, High Holborn, London.

FILMS.—No. 5,911. "Improvements in photographic films and apparatus connected therewith." Samuel Henry Adams, care of Adams' Hydraulics, Limited, Scotswood-on-Tyne.

CINEMATOGRAPH.—No. 6,068. "An improved cinematographic process." Robert Thorn Haines, 322, High Holborn, London.

CABINETS.—No. 6,150. "Improvements in or relating to cabinets for photographs and like articles." George Isaac Bakewell, 111, Hatton Garden, London.

PROJECTION APPARATUS.—"Improvements in optical projection apparatus." Albert Thornton Thompson, 322, High Holborn, London.

ILLUMINATION FOR ENLARGING APPARATUS.—No. 6,313. "An improved means of illumination adapted for use with photographic enlarging apparatus." Henry Rex Cook, Fort Fareham, Fareham, Hants.

IMPROVEMENTS.—No. 6,340. "Improvements relating to photography." John Page Croft, 18, Southampton Buildings, Chancery Lane, London.

CAMERAS.—No. 6,351. "Improvements in or relating to photographic cameras." Alfred Woods, 8, Quality Court, Chancery Lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

Specifications are obtainable, price 8d. each, post free, from the Patent Office, 25, Southampton Buildings, Chancery Lane, London, W.C.

SHUTTER.—No. 25,385, 1904. "Relates to improvements in photographic shutters for cameras patented on April 28, 1903 (No. 9,572). The object of the invention is to provide a photographic shutter for cameras which may be used for instantaneous or time exposures and which may be used to take an instantaneous picture when the curtain is moving in either direction, up or down. The object of the invention is, further, to provide means whereby the width of the slot in the curtain may be varied from the outside of the shutter casing and the width indicated to a nicety by means of a dial plate. The invention consists in improved mechanism whereby the width of the slot is regulated and recorded by a dial; again, in the improved mechanism whereby it is impossible to change the width of the curtain slot until one of the spindles is locked to the casing; and again, in the improved mechanism for setting the curtain for time exposures, as shown in 17 figures and specified in 23 claims." J. S. Wright, Duxbury, Plymouth, Mass., U.S.A.

New Apparatus, &c.

The Dark-Room Companion. Made and sold by The Tress Company, 33, Oxford Street, London, W.

A piece of apparatus which we have long held to be a most useful and time-saving device in the dark room at length reaches us from the Tress Company in very practical shape. It is simply a light-tight box or cupboard with a door in the front which moves up and down in grooves. Inside is a shelf, and the size of the interior is such as will accommodate 12 by 10 paper or plates. The service which this very simple fixture renders the photographer is the storage of his sensitive materials where he can get at them in a minute, and yet be sure that they are secure from light fog. One's packet of bromide paper is divested of its wrappings, placed in the "Companion," and piece by piece removed as they are wanted. To spare the worker both his hands for charging frames, etc., the sliding door is actuated by a pulley worked by the foot. The apparatus, which costs 12s. 6d., is one of those absurdly simple things which should certainly save much labour and worry; the surprising thing is that it has not been supplied before.

The "Tress" Flash Lamp. Made by The Tress Co., 33, Oxford Street, London, W.

The chief claims for attention made by this new flashlight apparatus are its extreme simplicity and effectiveness. It consists primarily of a shallow tray measuring about 24 inches by 12 inches, on which the necessary amount of magnesium or flash compound is burned, preferably with the assistance of gun-cotton. In front of the tray a wire frame is fixed, on which tissue paper or thin butter muslin is stretched to diffuse the light, and at the rear, a large tin reflector is placed. In the lower part of this reflector is a small circular hole, through which a lighted taper is passed to ignite the flash powder, the reflector itself serving to protect the eyes of the operator from the flash.

The lamp is supported on a staff, which slides into a socket underneath the tray, and this staff can be supplemented by others, fishing rod fashion, so that the lamp can be placed at any convenient height. The entire apparatus, with the exception of this supporting staff, folds up neatly into the shallow tray, and the reflector folds over and forms a lid, which holds the whole together. It can then be carried easily under the arm, as it does not exceed one inch in thickness. The apparatus is made of thin sheet-iron and tin, and is well and strongly finished, and, as an effective and powerful flashlight apparatus for small or large areas, would be difficult to beat. It costs 17s. 6d. complete.

"Zigo" Self-toning Paper. Made by Thomas Illingworth and Co., Ltd., Willesden Junction, London, N.W.

This self-toning paper appears to have become firmly established in popular favour, and the chief reason for this seems to be the ease with which tones from red to dark brown are obtained by the use of the hypo bath only. The makers inform us that the most recent batches have been even further improved, both in the matter of the emulsion and in the matter of the packing. Prints on "Zigo," which have been exposed for nine months to strong sunlight, have shown no deterioration whatever, except in the tone of the raw paper; and Messrs. Illingworth draw special attention to the fact that "Zigo" is made entirely by British labour, at their Willesden Works, which have a capacity for coating five miles of the paper per day.

Special points in connection with the manipulation of "Zigo" that

should be borne in mind by the printer are:—1. Print deeply. Zigo prints reduce somewhat in the hypo solution, though the image comes back again when dry. 2. Have hypo solution full strength, viz., 4 oz. to 20 oz. of water, that is 4 tablespoonsful to 1 pint of water. 3. Do not use the hypo solution when ice cold, it is better with the chill taken off. The temperature should not be less than 60 degrees F. 4. The tone or colour of the prints is determined by the strength of the hypo solution and by the length of time they are left in the solution. Toning commences as soon as the print is put in the solution, and continues until it is taken out. 5. Any tone can be obtained by varying the strength of the hypo solution. Weak solution gives red tones. Strong solution gives purple or brown tones. 6. A slight yellowness of the paper will not affect the finished print, it all comes out in the hypo. 7. For deep purple tones print deeper, and strengthen hypo solution.

A NEW catalogue of the Goerz-Anschutz Folding Cameras is to hand from C. P. Goerz, 4 and 5, Holborn Circus, London, E.C. It contains full information regarding these well-known cameras and the new pattern focal plane shutter. It is well illustrated, and will be sent free on application.

A COMPREHENSIVE catalogue of photographic requisites is just issued by James Woolley and Sons, Victoria Bridge, Manchester, and will be sent post free to any applicant.

BREATHLESS Photography.—After the Boatrace on Saturday last there followed another contest, which was as keenly contested and, to those concerned, was even more exciting than the event of the day itself. On Saturday evening four London music-halls were able to show animated pictures of the race, but few among the audiences realised the amount of work done at racing speed which such an accomplishment involved. Four machines were focussed on the race, each of them taking hundreds of photographs a minute, and all these hundreds of yards of film had to be developed and prepared for putting on the machines which were to show them at night in a few hours. Such feats have become almost the commonplaces of modern life; yet, remembering that they would have been absolutely impossible but a few years ago, they surely deserve to be ranked among its marvels. The public has almost ceased to wonder at seeing the events of the day shown as they actually happened upon a screen in the evening, and is growing accustomed to seeing photographs of the happenings of one day reproduced in the illustrated papers of the next morning. Yet both are astonishing feats, and the latter, with its added difficulty of making blocks from which the illustrations are printed, and the printing and distributing of hundreds of thousands of papers all over the kingdom, involves the employment of the most up-to-date improvements and the application of the utmost enterprise and energy from all concerned. For instance, the photographs taken at Aintree last week during the running of the Grand National Steeplechase were reproduced in the "Daily Mirror" appearing next morning. They were taken at Liverpool after three o'clock on Friday afternoon. The films for the Biograph Company, which arranged to show them at the Palace Theatre that night, were taken at the same time. The films and plates were developed in a specially equipped saloon carriage during the run from Liverpool to London, where they arrived at nine o'clock in the evening. After that came the race to the "Daily Mirror" office, the preparation of the blocks and plates for the printing machines, and the printing of the paper in time for the early morning distribution. Such feats are now expected; but it can be readily understood that the race to show photographs of such contests are as exciting as the contests themselves.

Meetings of Societies.

MEETINGS OF SOCIETIES FOR NEXT WEEK.

April.	Name of Society.	Subject.
7.....	Wimbledon and Dis. Cam. Club	<i>R. & J. Beck's, Ltd., Novelties. Demonstrated. Mr. W. F. Slater, F.R.P.S.</i>

THE PROFESSIONAL PHOTOGRAPHERS' ASSOCIATION.

THE annual dinner of the association having ceased to exist as an official fixture, it was decided, a few weeks ago, by the committee to hold a festive gathering on their own account to cement the good fellowship which has always been a great feature of their business gatherings. Accordingly, on the evening of Friday last, the 31st ult., a dinner was held at the Villa Villa Restaurant, Gerrard Street, W., at which thirty sat down, including several ordinary members of the association and a few guests. In the unavoidable absence of the president, Mr. T. C. Turner, Mr. Alfred Ellis, past president, presided; the vice-chairs being occupied by Messrs. Martin Jacolette, vice-president, and William Grove, hon. treasurer and secretary. Among those also present were Messrs. W. Downey, S. H. Fry, A. C. Banfield, H. S. Mendelssohn, P. E. Marshall (hon. solicitor), E. Scamell, Thomas Bedding (founder of the association), George E. Brown (BRITISH JOURNAL OF PHOTOGRAPHY), Alexander Mackie, D. Prodger, H. C. Spink (Brighton), R. Fellows Willson, H. E. Hull, Frank Turner, Alexander Corbett, Albert England, Stuart Debenham, etc. An extremely pleasant evening was spent, Messrs. Barkley Gammon, and Stuart Debenham adding to the enjoyment by their musical and vocal entertainment.

ROYAL PHOTOGRAPHIC SOCIETY.

MEETING held April 4, A. Haddon in the chair. Mr. A. G. Field gave a practical demonstration on "The Negative in Portraiture." The lecturer, who had brought all the paraphernalia of the studio with him, and was moreover assisted by a young lady model in fashionable evening dress and picture hat, was able to show in a convincing manner the various styles of lighting for effective portraiture. For the purpose of the demonstration a large "Ideal" magnesium light installation was used, and several negatives were taken with it. These were developed at once in the Society's dark-room, and passed round to show the type of negative required. Mr. Field referred to the various kinds of backgrounds in use in modern studios, and deprecated the use of vignetting when a dark ground was resorted to. He particularly impressed on those present the value of a high topside light for securing effective modelling of the face,

too low a light tended to produce flatness, while a top light only was of use to bring out character in a portrait, and was especially useful for old and lined faces. The head should always appear to be well balanced on the shoulders, no matter what the angle of the latter should be, and the camera should not be placed too high in the relation to the face. He recommended a model throne for the sitter, and suggested that a good height for the camera for average portraits was about the level of the chest. As regards studios, the lecturer believed in the old-fashioned studio with plenty of light, and roller-blinds; he did not think the single slant light was here to stay. The ideal studio should be lit from the N. or N.N.E., and should have a good topside light, with a capacity for side lighting also. The walls should be painted with a distemper of magnesium oxide to which a touch of pink had been added, or better still if the walls could be papered with white blotting paper. Personally he would like to have the studio glazed with yellow glass and the walls painted yellow; much finer portraiture would then result by using isochromatic plates, but the exposure would be excessive.

In the German studios beautiful low tone results were obtained by the use of a pink reflector, and in any case he preferred giving a long exposure whenever possible. An exposure of, say, 15 sec., provided the sitter did not move too much, or get up and walk away, gave a far better portrait than a quick exposure. This was due to the slight changes of expression that passed over the face during the exposure, and the portrait was, in effect, almost of a composite nature, reflecting the various moods rather than a fixed stare. The lecturer did not recommend the modern anastigmatic lenses for studio portraiture, or near-by portraiture out of doors, the flatness of the field was of no advantage to secure good modelling, which with a good portrait lens of the old type was obtained with ease, and in portrait studies the loss of marginal definition was of no consequence, as the centre of interest was the face. He recommended pyro soda as a reliable and well-tried developer, and suggested $\frac{1}{2}$ grain pyro to the oz. as a good proportion. To secure softer results, occasionally a little metal might be added to the formula, but in all cases the developer should be well diluted, with equal bulk of water at least, to avoid harsh contrasts. In practice he found that when a lot of portrait negatives had to be developed together three large developing dishes should be employed. In the centre one the dilute developer was placed, in the right-hand one a weak solution of bromide of potassium (about 2 per cent.), the left-hand dish should contain plain water of a temperature of about 70 deg. If the negatives, on being placed in the developer, showed symptoms of over-exposure, they were promptly transferred to the bromide dish; if under-exposure were apparent, they were placed in the water. In this way it was possible to obtain nearly all perfect negatives when a large batch of exposures were being developed by the operator in the dark room.

THE CRICKLEWOOD PHOTOGRAPHIC SOCIETY.—A lecture on "Troubles Commonly Met with in Using Dry-Plates" was given by Mr. J. Stevenson, of the Imperial Dry Plate Company, before the members of this society on Wednesday last. The lecturer showed a great number of plates which had been sent to the manufacturers for an explanation of failures which had occurred, chiefly through improper manipulation by beginners, but also by curious and out-of-the-way difficulties occasionally met with during ordinary practice. He showed the various forms of "pinholes" which might be met with, and pointed out that the real "pinhole" was caused by a speck of dust on the dry-plate during coating, or during drying after coating, but these now very rarely occur. Other so-called "pinholes," really spots, are often caused by dust on the plate during exposure or development, or by dust or air-bells in the developer. "Fog" is another occasional source of great trouble, and may be manifested

in many ways, some of them giving rise to bands and patches of uneven density, the cause of which is sometimes difficult to ascertain. He showed some very curious results caused by a small hole in the camera acting as a supplementary lens, and giving an image of the sun, which, through movement of the camera, took the form of irregular worm-like markings. Light reaching the plate through the corner or edge of the dark-slide sometimes gave rise to striking and curious effects. Mr. Stevenson said that there was a feeling on the part of photographers to blame the makers for any fault found in the finished result, although this feeling was not nearly so great as formerly. Plates are so carefully manufactured nowadays that defects are really reduced almost to vanishing point.

DENNISTOUN PHOTOGRAPHIC SOCIETY.—The members of this society assembled in their new rooms, 53, Roslea Drive, on Wednesday last, to hear Mr. Thomas W. Robertson, ex-president of the Glasgow and West of Scotland Association give the opening address of the season. The subject of the lecture was "Killin and District," and Mr. Robertson, who has visited it at all seasons of the year, showed about 120 lantern slides illustrative of its varied aspects.

NEWCASTLE PHOTOGRAPHIC ASSOCIATION.—Mr. C. T. Cothay, of Sunderland, lectured to the members of this association on Tuesday of last week on "Holidays with a Camera," illustrating his remarks by a series of excellent lantern slides depicting northern holiday resorts and views of the Shetland Islands and North of Scotland.

WHITBY CAMERA CLUB.—"Intensification and Reduction" formed the subject of a demonstration by Mr. W. Brown before the members of this society on Friday last. The lecturer, in commencing his demonstration, said that negatives were often being produced which required after-treatment, either by strengthening—commonly called "intensification"—or by weakening—commonly called "reduction." An over-developed negative, if flat, might be improved with the Howard Farmer reducer, made by adding as much 10 per cent. solution of potassium ferricyanide to ordinary hypo solution as would make it a sherry colour. This cleared the negative, and accentuated the contrasts. On the other hand, an under-developed negative, following an under-exposure, would require treating to a $2\frac{1}{2}$ per cent. solution of ammonium persulphate, the peculiarity of which was that it reduced the denser portion in greater degree than the thin parts. A stop bath of sodium-sulphite solution should be used when reduction had proceeded far enough. A thin, ghostly, under-developed negative could be brought up to printing density by using the ordinary uranium toning bath, such as was used for toning bromide prints or lantern slides. This gave a red colour to the film, varying according to the time of immersion, and, while causing slow printing, yet gave increased contrasts. Similar effects could be obtained by bleaching in mercuric chloride, washing, and then blackening in either a solution of ammonia or sodium sulphate, or re-developing with almost any developer. Ferrous oxalate he recommended for lantern slides. A mercuric iodide and sodium sulphite "Tabloid" intensifier was also used. A reducer made by adding to a saturated solution of iodine in alcohol as much of a saturated solution of potassium cyanide in water as would discharge the colour, was, when undiluted, an extremely powerful solvent of silver, but could be controlled by the addition of water.

THE SCOTTISH PHOTOGRAPHIC FEDERATION.—The meeting at Stirling last week was presided over by the new president, Mr. G. D. Macdougald, F.I.C. The recent Salon at Glasgow had been run at a distinct loss, although exact figures were not forward, but this loss will be undertaken by the guarantors, so that the finances of the Federation will not suffer thereby. The general opinion seemed to be that the Salon had not been long enough open to be fully known. It was regretted that it did not get the support

it deserved, even in some quarters where it might have been confidently expected. The 1906 Salon Committee was appointed as follows:—G. D. Macdougald, V. C. Baird, Arch. Campbell, and J. L. Scott. It was agreed that the annual excursion of the Federation be held to Blairgowrie on June 3, and the arrangements were left to the Blairgowrie Association. The President offered a silver plaque for competition in connection with the portfolio. The Council accepted the offer, and thanked the donor.

NEWCASTLE PHOTOGRAPHIC ASSOCIATION.—At a meeting of this society, in the Y.M.C.A. buildings, Newcastle, on Tuesday last, Mr. Charles Coothay, of Sunderland, lectured on "Holidays with the Camera." His subject embraced travel over a great portion of the British Isles.

EXETER CAMERA CLUB.—An effort has been made to reorganise the Exeter Camera Club, which has been dormant for two or three years. New officers have been appointed, and a short programme of lectures and demonstrations has been arranged for the remainder of the winter session. Excursions to places of photographic interest are being arranged, and hopes are entertained of the club attaining its former popularity. The club re-starts with a membership of about thirty. A demonstration on "Development of Negatives" was given by Mr. C. Cole, at the club's headquarters, Barnfield House, Exeter, on Monday. The hon. secretary is Mr. J. W. Lake, jun., 41, High Street, Exeter, and he will be pleased to hear from intending members.

CRICKLEWOOD PHOTOGRAPHIC SOCIETY.—Mr. T. M. Wilde having resigned the secretaryship of this Society, Mr. Wilfrid Emery has undertaken the duties *pro tem*.

On Wednesday evening last over eighty members of the Thornton Heath Photographic Society and friends enjoyed a *soirée dansante* at the Thornton Heath Public Hall.

An exhibition of "Advertising Photo. Studies" was opened at the Holborn Viaduct Hotel on Monday, and will remain open until the 15th inst. The exhibition is under the direction of the F. E. Coe Advertising Agency, Ltd., and the photo. studies are by Mr. J. Ellsworth Gross, of Chicago. Mr. Gross is responsible for most of the photographs used so liberally by American advertisers, and he is becoming recognised in the States as being right on the top of his particular business. Over eight hundred different studies are on view and they comprise photographs that can be applied to practically every kind of business that can be made the subject of pictorial advertisement. We commend this exhibition to our readers' attention as showing one of the practical applications of photography to modern requirements.

DEATH of a Veteran Photographer.—Many in York and the North of England will learn, with great regret, of the death of Mr. William Pumphrey—who for many years lived in York and the neighbourhood—which occurred in Bristol on Tuesday of last week, at the advanced age of 88 years. Mr. Pumphrey commenced business in the 'forties' as a photographer, in partnership with Mr. William Monkhouse, and he was the earliest in York and for twenty miles around to introduce the daguerreotype process. Retiring from business rather more than forty years ago, he entered public life in the city, and his lantern lectures and chemistry classes are remembered for the instruction they afforded. The lectures were the predecessors of the University Extension lectures of the present day. He was a prominent and active member of the Society of Friends, and did much good work in York. Continental travel, scientific experiments, and photography were occupations which he pursued with energy; and he was a member of the Microscopical Society, and president of the Photographic Club at Bath.

News and Notes.

A POSTCARD Pioneer.—We confess to a complete and mystifying ignorance as to what becomes of the vast numbers of postcards which pour forth from the presses of the great stationery houses; but if, as is reported, they bring delight to the heart of the suburban girl and the innumerable class of persons in their teens whose joy in life is still unabated, then the satisfaction of administering this consolation should be keen in the breast of giants in the postcard publishing trade, such as Mr. F. T. Corkett, manager of Messrs. Raphael Tuck's postcard department. We understand, however, that the feelings which do actually impel these gentlemen to pursue their avocations are of quite another character, and avowedly less magnanimous. Mr. Corkett, recently interviewed by the "British Printer," confesses to employing thirty artists and six out-door operators, and to producing 2,000 different originals during the past twelve months. Messrs. Raphael Tuck order their board for postcards 100 tons at a time. Apparently, 100 tons of cardboard does not appease the postcard public very long.

PHOTOGRAPHING the Pope.—The distinction of being summoned to Rome to photograph the Pope has fallen to the firm of Histed, of Baker Street. In the Vatican the photographer was allowed to choose from among a number of splendid apartments one that might serve as a studio. The sitting took place at half-past eight in the morning, and Mr. Histed states:—"His Holiness was perfectly delightful to photograph. He made such a splendid picture, with his fine muscular frame and massive head. Plate after plate was exposed, the Holy Father watching the operations with the greatest interest, and making continual comments to his private secretary. Once when he was smiling all over his face I ejaculated, 'Oh, if he would only keep that pleasant expression for a moment.' The secretary at once translated it into Italian, and his Holiness went off into a hearty roar of laughter. 'Too bad,' he said, 'don't I always look pleasant?'" Finally the photographer ventured the request that he might be allowed to take a photograph of his Holiness in the act of conferring a blessing. This was graciously acceded to, and should make a notable picture.

With regret we have to record the death of Dr. E. Holm, one of the scientific staff of the well-known optician C. P. Goerz. Dr. Holm was a constant contributor to German photographic literature, and the author of several works on photography.

YORKSHIRE Photographic Union.—The annual meeting and exhibition of prints will take place in the Grammar School, Manor Row, Bradford, to-morrow afternoon (Saturday). Mr. Godfrey Bingley will give his presidential address in the evening, and the following gentlemen will address the delegates on photographic topics:—Alex. Keighley, hon. treasurer, subject, "Artistic Perception"; Percy Sheard, vice-president, will read an extract from the minute-book of the "Garden Camera Club"; Percy Lund, vice-president, subject, "On Making Use of Photography."

"CRIMINALS Caught by the Camera" is the title of an interesting article in the current number of "Tit-Bits," and many interesting instances where photography has assisted the police are recounted. It appears that the photographing of habitual criminals in our prisons for the purpose of police identification dates back as a regular system to 1870. It is an extraordinary fact that a considerable number of newspapers at the time opposed the innovation in the strongest terms. It was urged that there were so many criminals that to photograph them all would take the police all their time;

that it was an outrage to photograph a man against his will; that one criminal was so much like another that photography would not distinguish between them! In spite of all these absurd objections, however, the police got their way, to the dismay and disgust of the criminal population, and by the end of 1872 the Commissioners of Metropolitan Police had collected in the Habitual Criminals' Office no fewer than 43,000 photographs of undesirable characters.

LORD EDWARD SPENCER-CHURCHILL is an expert amateur photographer, and one evening last week, in connection with the Windsor Camera Club, provided an exhibition of photos taken mainly by himself while on the voyage to the Cape on the Walmer Castle and in South Africa.

A GREAT historical pageant is in active preparation at Sherborne, Dorsetshire, to commemorate the 1,200th anniversary of the founding of the town, bishopric and school by St. Ealdhelm, A.D. 705. The pageant, which takes the form of an unique folk-play, specially written and invented by Mr. Louis N. Parker, deals with the chief historical events of the interesting town of Sherborne, and will be presented in the ruins of the Ancient Castle on June 12, 13, 14, and 15. No more fitting stage could be found, and the town, with its rich historical associations, should draw large numbers of visitors to witness this interesting out-door play, which will be entirely performed by the townspeople of Sherborne.

THE Postal Camera Club.—The P.C.C., which may be regarded as the premier organisation of its kind in this country, is about to suffer a loss by the resignation of its hon. secretary, Mr. W. R. Bland. Postal photographic clubs have long been regarded as the only possible solution of the difficulty of bringing earnest workers, living in widely separated parts of the kingdom, into close touch with one another, not only for the purpose of mutual help and criticism, but also for bringing out that vitalising desire to excel in competition that is inherent in every ardent exponent of his craft. That such clubs succeed in serving this purpose is evidenced on every side, not only by the two dozen or more flourishing British postal clubs now in existence, but also by the great number of inter-society circulating portfolios, which in many instances prove the secret of the society's strength and utility in the photographic world. The P.C.C. has been, and still is, probably the most conspicuously successful of the clubs with pictorial intentions, and when it is conceded that no matter on what lines such a concern is run, it will sooner or later collapse if no strong guiding spirit manifests itself to organise and look keenly after its interests, to preserve unity of purpose, and judiciously suppress any indication of cavilling criticisms, and above all to ensure the punctuality of dispatch of the folios from one member to another. The P.C.C. was exceedingly lucky in 1895 in finding in Mr. Bland a secretary who has proved capable of doing all this and more, and who was possessed of all the attributes necessary for keeping up the business end of the club in addition to ranking high among the best pictorial workers in the country. His influence has had an undoubtedly beneficial effect on the work of the club, and it is noteworthy to observe that during the past few years its members have taken more medals at the Royal Photographic Society than have the whole of the members of the Society itself. It will be gratifying, therefore, to the members of the club to learn that Mr. J. C. Warburg, who has identified himself not only with the Postal Camera Club, but with many forward pictorial movements, is to carry on the duties of hon. secretary.

THE "Southern" Exhibitions, 1905.—The Southampton, Hove, and Southsea Societies have fixed the dates of their exhibitions as follows:—Southampton, November 21-25; Hove, December 1-6; Southsea, December 12-20.

Commercial & Legal Intelligence

A PHOTOGRAPHER'S Misfortunes.—At the Leeds Bankruptcy Court, Wm. Elland, 81, Hill Top Mount, carrying on business as a photographer at 14, New Briggate, returned a statement of affairs showing liabilities £536, and assets £178. For twelve years bankrupt was manager for a wholesale firm of photographers at Manchester, after which he became secretary and manager for Eddison and Co., Ltd., in Leeds. He invested £500 in the concern, and in 1897 he purchased the branch business at New Briggate for £600.

A CHESTER Chemist's Affairs.—Ernest Williams, photographic dealer and chemist, lately carrying on business in Chester, attended for his public examination at the Chester Bankruptcy Court on Tuesday last. The liabilities are expected to rank at £1,826, and the deficiency is £1,620. In March, 1899, he took over the business of Mr. Kemp, chemist, Chester. It was valued at £1,536, and he paid £900 down, which he borrowed from relatives. The turn over was about £1,400 a year, and the gross profits 27½ per cent. The examination was closed.

A RECEIVING order was made at the Leeds County Court, on Thursday last, on the debtor's petition, in the case of Cecil Montague Stafford, of 2, Commercial Street, Leeds, photographer, residing at 5, Nassau Place, Chapeltown Road, Leeds.

THEATRICAL Photography does not Pay.—Jules Inger, of Denman Street, Piccadilly, a theatrical photographer, appeared at a first meeting of creditors and the Official Receiver last week. His business had been carried on under the style of the Tamesis Syndicate, and after the retirement of his partner he (debtor) carried it on alone, trading recently in Denman Street, W. In November last a company was formed for the purpose of taking over the business, together with his liabilities and assets, and he acted as managing director until the date of the receiving order. The debtor further stated that he was an undischarged bankrupt, and attributed his present position to the failure of the company to satisfy the whole of the liabilities which it had taken over from him.

NEW COMPANIES.

CHARLES WALKER (Harrogate), LIMITED.—Registered March 23. Capital, £1,000 in £1 shares. Object: To acquire the business carried on by C. Walker at 11, Coldbath Road, Harrogate, and to carry on the business of chemists, druggists, drysalers, dealers in photographic apparatus and materials, oil and colour men, importers and manufacturers of and dealers in pharmaceutical, medicinal, chemical, industrial, and other preparations and articles, etc. Registered office: 17 and 18, Quebec Street Chambers, Leeds.

E. H. HALL, LTD.—Registered March 21, by Jordan and Sons, Ltd., 120, Chancery Lane, W.C. Capital, £2,000, in £1 shares. Object: To acquire the business carried on by E. H. Hall at 60, Church Vale, Handsworth, and to carry on the business of chemists, druggists, opticians, dealers in all kinds of salts, acids, alkalis, drugs, photographic requisites, and scientific, surgical and optical instruments, etc. Registered office, Church Vale Drug Stores, 60, Church Vale, Handsworth.

THE Peripatetic Kodak Exhibition was opened at the Queen's Hall, Edinburgh, on Tuesday last, by the Lord Provost, Sir Robert Cranston.

EASTER Holidays in Holland.—Mr. W. F. Slater sends us a programme of a personally conducted photographic excursion he is organising for Easter to Volendam on the Zuyder Zee. Intending participants in the outing should communicate without delay to Mr. Slater, 84, Longhurst Road, Lee, S.E.

Correspondence.

*** Correspondents should never write on both sides of the paper. No notice is taken of communications unless the names and addresses of the writers are given*

*** We do not undertake responsibility for the opinions expressed by our correspondents.*

THE P.P.A. ASSISTANTS' CERTIFICATES.

To the Editors.

Gentlemen,—I note your remarks in connection with the P.P.A. assistants' certificates scheme in yesterday's "Ex Cathedra."

I am in the position of the branch-managing operator you exemplify, and have considered the published note of second-grade qualifications for certificates with some considerable doubt. It occurs to me that the grading between that and a first-grade certificate is too wide and abrupt to satisfactorily include all those who occupy situations other than those of the "hundred or so studios" that you mention.

If an applicant could be assured that a second-grade certificate will give a sufficiently high standard of certified workmanship, I have no doubt that the P.P.A. would receive filed applications in sufficient numbers to prove gratifying, in contrast to the disappointing "few" you are informed of. I do not think the fee difficulty that you refer to is the major reason for the want of enthusiasm, but, rather, so far as first and second grade certificates are concerned, at least, to the steepness of gradation that occurs between them.

There are many operators who may be justified in assuming themselves qualified for first-grade certificates to whom, apparently, the conditions of the second grade apply inadequately. They have not had opportunity, perhaps, to engage in the very highest class of work, nor can they all be competent in electric and other methods of artificial lighting, but yet are capable of work of good standard that five years' (minimum) experience, etc., could not justify. They are debarred from taking first-grade certificates because their work is not representative of the class of the "hundred or so studios" that you refer to, and the result is dissatisfaction, which, I must confess, your remarks, however assuring they may appear to be, do not dispel.

I would suggest that a special class might be instituted, termed, say, "Extra first-grade," that would apply to those operators whose exceptional experience and ability would command it, and that the first grade be available to such applicants as those I have indicated. The second grade could still occupy the same place and under the same conditions—and the third grade the same.—Yours faithfully,

Scor.

[Several other letters on this subject received as we go to press are held over until next week.—Eds., B.J.P.]

"DEVELOPMENT FACTOR."

To the Editors.

Gentlemen,—There is an old proverb that if you give a misstatement a day's start you can never overtake it. Someone at a recent meeting of the Royal Photographic Society appears to have stated that I have used the term "development factor" in a sense different to that of Hurter and Driffeld, and that a confusion of terms has resulted. Since then, I have been busy writing to editors and others denying the statement; but unfortunately it appears again in your issue for March 31.

Let me state emphatically that I have never since 1894 used the term "development factor" in any other sense than that used by Hurter and Driffeld. For at least eleven years I have, in writing of

my system of factorial development, invariably and consistently used the term "multiplying factor" for the factor necessary to my plan.

It is, I always think, rather unfortunate that Hurter and Driffeld adopted the word "factor" for what is really only the measurement of a result, but I have always respected their prior use of the term "development factor." If the index of the "Watkins Manual" is consulted, it will be found that I have kept perfectly distinct the two terms "development factor" and "multiplying factor."—Yours truly,

ALFRED WATKINS.

Hereford, April 2.

[We are glad to have Mr. Watkins' assurance that the confusion of terms is not his, and a review of his writings and of the instructions issued by the Watkins Meter Company is sufficient to convince us of his innocence in recent years. He will pardon us, though, if we remind him that in his first paper, "A Method and Instrument for Timing Development," before the Central Photographic Club, and reprinted in our pages on February 23, 1894, the expression "development factor" is used throughout. The eikronometer, he says, "will automatically multiply by the development factor." If we saddle Mr. Watkins with the onus of guilt in the first instance we will do him the justice of stating that the term does not occur in his subsequent papers.—Eds., B.J.P.]

THE INVENTOR OF "GUM."

To the Editors.

Gentlemen,—It seems quite a singular coincidence that only the day before your last issue (in which "Historicus" referred to my father) that, having occasion to shift some things in a cupboard of the room he worked in during the later years of his life, I came across a box of letters carefully sorted in bundles, each person's by themselves, and in their respective envelopes. On the first one I noticed the name "Annan," and I knew these would be business letters; but, with no intention of going through them, I opened about three of them. As one of these so thoroughly bears out the remarks in your issue of March 24, allow me to quote from it, because, quite incidentally, it proves *how much he had succeeded* in what was then undoubtedly his greatest desire—to produce good copies of oil paintings in oil colour so that people of moderate means might be able to possess such as near as possible to the originals, which only the wealthy could possibly have.

As at this time he was most anxious to be tested by independent people, it would seem from the wording of *this reply* that he had suggested to Mr. Annan to borrow a good picture that he might produce a copy to prove still further what he could do:—

"Glasgow, December 29, 1871.

"... I am looking out for a picture to *purchase* that I may take a negative for you as a companion to the one you have done. I would not like to ask a loan of a picture from a friend to make *such an exact copy* as you can make.—Yours truly,

"THOMAS ANNAN."

One cannot but admire Mr. Annan's proposal to purchase. It will be seen, however, that no copies of an original could be used commercially without first obtaining permission of the owner of the copyright.

I should like next week to give you an extract of a letter of recent years, since his death, which almost unintentionally proved also the excellence of his work in this direction. It is not a little remarkable that in this direction the very excellence was used by some as a barrier to the work, while in the early days of the gum-bichromate process those who tried the most to throw cold water on his work did so because the results would not compare with the fine texture of an albumen print, though I have still some of his earliest produc-

tions which for fineness of gradation and half-tone will compare very favourably with any that are done to-day; the fact is, these critics expected too much for quite a new departure, and if he had not had a good amount of grit in him he would have been discouraged.—Yours truly,

W. POUNCE.

Dorchester, March 28, 1905.

THE EDINBURGH PHOTOGRAPHIC CLUB AND THE SCOTTISH FEDERATION.

To the Editors.

Gentlemen,—Would Mr. McCulloch kindly give the reason why the Edinburgh Photographic Club rescinded its resolution to join the Scottish Photographic Federation. If the facts as generally current in Scotland were known to your readers, they would put a very different complexion on Mr. McCulloch's statements. I also note he disparages the Club, carefully omitting to state its membership is limited to forty, also that entry is difficult. In conclusion, I would ask: *Has the Edinburgh Photographic Club withdrawn from the Federation?*

AN ASSOCIATE OF THE S.P.F.

WANTED, A WORD.

To the Editors.

Gentlemen,—Through the medium of your journal, will you permit me to ask why photographers, in one important particular, should remain in the rear of almost all departments of trade and science?

No alternative terms for "photographs" and "photography" being recognised, it becomes necessary, in many establishments, to write or speak these words, each of eleven letters, hundreds of times in the day; it is therefore impossible to estimate the time wasted in typing or writing. The thought is overpowering.

No business man can correspond, either by letter, order, memorandum, or invoice, without sorely feeling the lack of shorter substitutes for expression, as noun or verb.

With very little delay, "wire" and "cable" supplanted "telegram"; who now thinks of using the whole word "bicycle"? While we, ourselves, should groan, had we to adhere to "hyposulphite of soda" and "pyrogallie acid."

Unhappily, also, abbreviation is impossible; we cannot write to our clients concerning "the phogh" or "the photh." While "photo." may occasionally be in use, it is quite too suggestive of "Arry" to be adopted in a good-class studio. "Pho."—"We wish you to pho. our premises, etc."—hardly meets the need.

This matter, being of almost international importance, might perhaps claim the attention of the P.P.A.

Probably the announcement of a prize would bring in an acceptable and comprehensive appellation.—Yours,

ECONOMIST.

[We must confess that the disability made much of by our correspondent had not impressed us as it has him; and we are not in the slightest sympathy with his object. Attempts to expunge the current words "photograph" and "photography" from the vocabulary seem to us as hopeless as they are ill-advised. Certainly we would discourage the use of the vulgarism, "photo," by professional photographers.—Eds., B.J.P.]

THE largest efficient telescope in the world is to be added to the equipment of Harvard University. The new instrument is 27 feet in focal length and has a 5-foot aperture—nearly twice as large as the Lick Observatory telescope, which has a 36-inch aperture. The telescope will be used chiefly for photographic work.

ST. ALBANS Photographic Society.—The first exhibition of this Society was opened last week at the Museum, St. Albans, and has proved an unqualified success.

Answers to Correspondents.

- * *All matters intended for the text portion of this JOURNAL, including queries, must be addressed to "THE EDITORS, THE BRITISH JOURNAL OF PHOTOGRAPHY, 24, Wellington-street, Strand, London, W.C." Inattention to this ensures delay.*
- * *Correspondents are informed that we cannot undertake to answer communications through the post. Questions are not answered unless the names and addresses of the writers are given.*
- * *Communications relating to Advertisements and general business affairs should be addressed to MESSRS. HENRY GREENWOOD & Co., 24, Wellington-street, Strand, London, W.C.*
- * *For the convenience of Readers, our Publishers, MESSRS. HENRY GREENWOOD & COMPANY, of 24, Wellington-street, Strand, W.C., undertake the registration of copyright photographs at a charge of 1s. 7d. each photograph, to cover cost of registration fee, form, etc. Two unmounted copies of each photograph must be sent with the fee.*

PHOTOGRAPHS REGISTERED:—

- W. T. Carter, 43, Drake Street, Rochdale. *Photograph of A. G. C. Harvey, Esq. Photograph of Ryland Adkins, Esq. Photograph of the Venerable Archdeacon Wilson, D.D.*
- J. J. Wright, 125, London Road, King's Lynn. *Photograph of the King's Lynn Football Club, Season 1901-1905.*
- M. H. Grocock, Laurel Cottage, Ulverston, Lancs. *Photograph of Mr. W. Symon.*
- J. A. Stelling, "Modena," 60, Peckham Road, S.E. *Photograph of the Rev. M. Cumming.*
- J. R. Browning, 11, Bedford Circus, Exeter, Devon. *Three Photographs of the Mayor of Exeter (C. E. Perry, Esq.) Driving a Tram Car.*

COPYRIGHT.—We have taken a series of photographs which we are having reproduced in colours as postcards, which we intend to copyright. Will you kindly inform us whether it would be best to copyright the original photographs or the finished postcards?—**ARTEX.**

We think it will be quite safe to register the original photographs, which, we take it, are absolutely identical with the cards, save that the latter are coloured. The case of another querist this week involves the same point, but his conditions are somewhat different. See reply to "B. S."

BROMIDES, ETC.—1. Can you please give us any information as to producing bromide enlargements without the customary washing of the papers, as we are informed this is being done? 2. We would also like to know how the bromide postcards are done—while you wait? 3. Do you issue a photographic directory? and, if so, can we obtain one from you?—**MARKS AND CO.**

1. We presume that what is meant here is the elimination of the hypo by chemical means. There are several preparations on the market which effect this, such as Hypax, sold by Griffins; Thioxydant, by Lumières; and Bayer's Hypo Eliminator. The print, after a short rinse, is immersed in the solutions and then again washed; see also article p. 244 last week. 2. If the cards are produced from a negative taken at the time, they must be, of course, squeezed to the wet negative and developed and fixed, and then treated with a hypo eliminator. 3. So far as we know, there is no photographic directory in existence.

CRIMSON TONES ON P.O.P.—Some months ago you gave a formula for obtaining crimson tones on P.O.P., unfortunately, in our spring clean, the B.J. has been burnt or thrown away. Do you mind repeating?—**TROUBLE.**

In our issue for January 13 Herr Kessler states that on matt collodion paper, red and reddish-brown tones may be obtained by using: Prepared chalk, 1 oz. (25 g.); water, 35 oz. (1000 ccs.). Shake well and allow to settle, and two hours before use add the clear supernatant liquid: Chloride of gold (1 per

cent. solution), 168 m. (10 ccs.). Another very good formula is: Thiocarbamide, 20 gr. (1 g.); water, 2 oz. (50 ccs.). Add enough of this solution to: Chloride of gold (1 per cent. solution), 1 oz. (25 ccs.) to dissolve the precipitate first formed. Then add: Tartaric acid, 10 gr. (0.5 g.); water to 40 oz. (1000 ccs.). Wash the prints well before toning. This acts very quickly, and it is as well to double the quantity of water in order to make it act more slowly. Another good formula, and one that we have found very satisfactory, is: Uranium nitrate, 1 gr. (2 g.); thiosinamine, 5 g. (10 g.); water, 1 oz. (1000 ccs.). Immerse the prints, before toning, in salt and water, and then well wash, and wash after toning.

WESTBANK.—(1), (2), and (3). We should say (2) holds out the best prospects; the other two are trade secrets, and unless you have some considerable chemical and technical experience you are not likely to make much headway. Write to the Regent Street Polytechnic, or the Bolt Court School, Fleet Street, for prospectus of instruction in "process." (4) Yes. Messrs. Elliott and Sons.

TORQUAY.—Technically your prints are of very good quality indeed, and admit of little improvement. Pictorially they do not rise much beyond the guide book or topographical stage. No. 1 contains far too much niggling detail, and the interest is scattered. It contains sufficient material for half a dozen pictures. No. 2 is better, but even here no attempt appears to have been made to concentrate the interest, and the lines of the composition lead the eye out of the picture. The district portrayed appears, however, to contain much pictorial matter, and first-class pictures should be obtainable there. Try again and let us see your results.

L. R.—We believe cameras can be classed as tools and, if there are other goods, cannot be distrained.

FINISHING BROMIDES.—Can you tell me if bromide paper requires coating with any solution previous to finishing with brush, so as not to show the working when viewed in a different light from that in which it is worked?—**INQUIRER.**

No coating is required. But avoid the use of gum with the colour, unless the paper is very glossy. Have you read the articles on "Finishing" that appeared in our issues for January 13, February 3, and March 17?

COLLOTYPE VARNISH.—Will you please give me the recipe for varnishing imitation P. O. P.'s (in colotype)?—**OWEN.**

Mastic, 30 parts; oil of lavender, 5 parts; alcohol, 150 parts; benzole, 40 parts. This mixture is kept for a week with occasional agitation, and the clear liquid is finally drawn off. It is applied with a broad brush, and the prints dried in a warm place. Or the prints may be floated on a water varnish made by boiling 60 parts white lac in 1,000 parts of water in which is dissolved borax, 60 parts.

COPYRIGHT.—I have two composition pictures made by aid of photography. I should like to copyright same, but as in each case much additional matter has been added in the finishing of the enlargements (pastel), I do not know how to proceed. Will you kindly tell me whether prints made from copy negatives should be sent, or, if not, what I should do? Of course, it is the originals (as worked up) that I wish to be copyrighted; not merely the copies therefrom.—**B. S.**

There is no reason to doubt that registration of the copies of the worked up original will be sufficient to protect the latter.

J. HARRIS.—As a mere size, we should say that you have plenty on the card, but if you want to make the card absolutely impermeable, you would have to put a much thicker coating on, and use a little alum. Write again and let us know exactly what you want, and whether the emulsion is to be printed out or developed.

B. W.—There is no other work that treats of the subject.

COPYRIGHT.—I am the author of a landscape negative which has never been published or registered. I sold the negative to a firm of publishers. Cannot they copyright the negative as their own? I think they can, but am not sure. Can you put me right?—THIRTY YEARS' READER.

Neither of you can register the copyright, as it has been destroyed by the sale of the negative before registration.

WOULD-BE ADVISER.—The value of a business is usually based upon the average of the three previous years' profits, and the present value of the stock, apparatus, etc. The prices obtained is also a factor in the case. High prices, of course, for the same returns, involve less labour and supervision than in the case of a cheap trade. A useful article on "Goodwill" appeared in THE BRITISH JOURNAL OF PHOTOGRAPHY for July 25, 1902, p. 585.

MOISTURE IN STUDIO.—I had some additions made to my studio two years ago, built of wood, and roof covered with felt—ridge roof. In the winter I find the frost comes through very badly. As soon as the fire is lighted it drips from the roof almost like a shower bath; the other parts, which are about twenty years old, do not do this. Can you suggest any cause for it? The first winter there was only one coat of tar on it, and that, I think, was rather thin; but last summer I gave it a thorough good coating, but I saw no difference this winter. The wood seems perfectly good. I have seen the roof dripping after one hour's mild frost (I am writing about the interior). I shall be much obliged if you can give any explanation.—W. MAYOR.

The cause is that the studio is badly ventilated, consequently, when it is heated, the moisture in the building condenses on the roof and then drops down. The remedy is to have better ventilation, so that the moisture can escape instead of condensing on the colder portions, as the roof.

ARE CAMERAS TOOLS?—Can cameras in a studio be distrained on for rent or debt, or are they classified with tools?—S. W.

We should assume that cameras and lenses are tools, and they cannot be distrained upon if there are sufficient other goods to satisfy the distraint. Even if there are not, they will be privileged provided they are in actual use at the time, we should surmise. We cannot call a case to mind that has been decided in a court of law as to whether photographic apparatus has been classed as tools or not.

DOUGLAS KENNEDY.—We are much obliged for the prints you send, but the subject has been nearly exhausted, and is of little practical interest.

WASHING PRINTS.—After fixing for ten minutes in hypo, what is the shortest time hypo can be eliminated (say, two or three prints only) of "rubbing down" water?—ENQUIRER.

See article in last week's B.J. : "Short versus Long Washing."

LOCAL REDUCTION OF NEGATIVE.—Can you inform me if there is any method of "rubbing down" a film to reduce it locally with spirits of wine.—S. E.

Lay the negative—film or glass, it does not matter—on a soft support, a few sheets of blotting paper, and rub with a bit of chamois leather, drawn tightly over the finger, and moistened with spirits of wine.

F. R.—1. It is yours if your purchase includes copyright: it is usual to state this item in the terms of sale. 2. Yes; you can register the transfer. 3. Anything from half-a-guinea.

CARLO.—1. We think not to be of much use. But if the wall itself were whitewashed, you would get a large amount of light reflected into the studio that would be useful, as it would be, practically, a side light. 2. A little more glass in the roof would be of service, but we do not see that any advantage would be gained by increasing that at the side. 3. It is doubtful, judging by the sketch, if the advantage gained would repay for the expense incurred. It appears to us that you will have to make the best use you can of the top light, of which there seems plenty, aided by screens and reflectors.

LENS QUERY.—I feel in doubt which kind of lens, of a good make, I ought now to purchase for a studio about 17 ft. long, and a very dull one. Whether a 3 B portrait would be the best, or an anastigmat lens, at the present time. I want same to take children very quickly; and have the sharpness combined. If an anastigmat would answer for out-door work, what kind would I require to take photographs up to whole-plates? How they describe same for this size?

The "3 B" would be, decidedly, the quickest lens for portraiture, inasmuch as it has an aperture, approximately, of $f/3$, whereas the largest of that of the majority of anastigmats is $f/6$. Consequently the latter will require somewhere about four times the exposure of the former. A 3 B will do very well for half and three-quarter length portraits in a studio 17 ft. long, but will be too long in focus for full lengths of the cabinet size. An anastigmat would be the best for out-door work. Better get a list from one of the makers of them; they will give you the information as to the focal length required for different sized plates.

"BLACK AND WHITE."—I permit me to ask you to have the goodness, and to send me an explication for the expression to work up *black and white*; if that will say negat. and posit., or if it is one expression for different whites to work on bromide paper; also P.O.P., is that one paper matt? With consideration, yours, ALFRED RICHTER, Monaco.

"Black and White" is a process of retouching bromide prints in dark and light chalks. Matt brands of P.O.P. are made.

G. W. W. (Doncaster).—Apply to the Professional Photographers' Association, 51, Baker Street, London, W.

H. H.—No, zinc will not do, as some of the silver will be deposited on it. You should get a paraffin cask.

R. G. AVERZATHY.—We cannot say; but you can get it from Dawbarn and Ward, Ltd., 6, Farringdon Avenue, London, E.C.

P. J. S.—We think they have not broken faith with you.

**** NOTICE TO ADVERTISERS.**—Blocks and copy are received subject to the approval of the Publishers, and advertisements are inserted absolutely without condition, expressed or implied, as to what appears in the text portion of the paper.

EX CATHEDRA.

The Fox-Talbot Memorial.

The final report of the committee which in 1896 undertook to raise funds for the restoration of the chancel of Lacock Church as a memorial to Fox Talbot, has now been published. The total amount subscribed is £990, and the cost of the restoration appears to have been just over £1,000. With the exception of one or two names, the list of subscribers is made up entirely from ladies and gentlemen not directly interested in photography, a fact which cannot be construed into a reflection on photographers' esprit de corps, for the form of the memorial is not one that we can regard as attracting the sympathy and support of photographers, however highly they may value the labours of Fox Talbot. We can congratulate the committee, however, on having raised a large sum of money, though we feel bound to deplore the form which the memorial has taken.

Duty Free Alcohol.

The outcry of manufacturers for the use of duty free alcohol, which has been very much to the fore of late years, resulted in the appointment of a committee on the subject, and the Chancellor of the Exchequer, when introducing his Budget on Monday, said "The other committee, the appointment of which arose out of our Finance Bill discussions of last year, was appointed to inquire into the facilities which now exist for the use of alcohol for industrial purposes, and to recommend any changes which they might think necessary, with a view to facilitating the development of our trade. Their report reached me a few days ago, and will be in the hands of members within a very short time. It proposes certain changes in our regulations, some of

them of a rather technical character. On the consideration which up to the present I have been able to give to them, I hope to be able to adopt the whole of these recommendations, which, however, will require legislation, and must form the subject of a separate measure. They will, I believe, remove difficulties which have existed in the use of alcohol in certain trades, and I hope they will be accepted by all concerned as a satisfactory solution of a very difficult and complicated problem."

Advice on Advertising.

Supplemental to the series of articles by Mr. Casey, which concluded last week, we publish to-day some notes and suggestions by one who is not connected with photography, save through a very intimate association with certain departments of technical advertising. Such aids to the business management of a studio, we would believe, should prove of value to a large proportion of the profession. Leading photographers can afford to neglect them. Their scheme of advertising must be individual, and cannot be prosecuted along anything like a beaten track. But the articles aim at suggesting to the middle class professional how he may make the most of the available channels of advertisement.

The Photographic Trade Exhibition.

The exhibition opened at the Portman Rooms, Baker Street, London, on Friday last, should do much to acquaint the visitor with the condition of the photographic trade in England at the present time. Overlooking the fact that one or two of the leading firms are conspicuous by their absence, the exhibitors make a brave show that will do much to strengthen the optimistic tone that is beginning to be heard in many quarters regarding the prospects of the trade in the immediate future. It appears from a general survey of the show that the tendency is all towards cheapening apparatus, etc., for photographers' use, and apart from the cameras and materials specially provided for the professional, small and effective cameras and time and labour-saving devices are in the majority. No doubt the increased facilities for obtaining large pictures by means of the many enlargers now on the market account for the former, and doubtless the voice of the amateur, heard loud o'er the land, is largely responsible for the latter. Compared, however, with the last exhibition of the kind, held in the same rooms in April, 1902, there is a marked falling off in the number of firms exhibiting their goods. On that occasion there were 89 stalls, occupied by 55 exhibiting firms. This year there are 72 stalls, and 41 firms only are represented, but nevertheless the note that is sounded by the exhibition is a healthy one, and signs are not wanting on every side to convince the most sceptical that the corner has been turned, and the

times of depression complained of last year have given place to brighter prospects for the ensuing season.

Latitude in Exposures.

A pull which the present day worker has over the earlier photographers, is the combination of speed and latitude in the best modern dry plates. We might almost safely say that the last five years has quadrupled the latitude of the moderately rapid plate of a speed of about 200 H. and D. In actual practice this means that a plate may be used of speed sufficient to enable rapid exposures being made, and yet exposure need not be adjusted with the accuracy necessary with much slower plates a few years ago, when it was well understood that a too full exposure rendered it almost impossible to obtain printing density. This gain in latitude arises principally out of new methods of obtaining density-giving qualities in modern emulsions. We have made a number of tests on a plate of about 250 H. and D. which has recently been placed on the market, and find that two seconds being the approximately correct exposure, plates exposed for two, four, eight, and sixteen seconds, all gave satisfactory negatives when developed in the same dish and for the same length of time. Such a difference as that between two and sixteen is hardly likely to occur with a reasonably careful operator, and with such plates there need be no fear of serious over-exposure. The importance of having the mind free from the worry of accurately adjusting exposure in portrait work is alluded to in another paragraph.

Expression in Portraits.

We have quite recently had before us a number of portraits taken by budding professional photographers, and the prevailing characteristic is an almost entire absence of any indication in the portrait of sympathy between the photographer and the sitter. Reasonably adjusted exposure, carefully arranged lighting, and satisfactory posing—but nothing more. Speaking generally we should say that the single quality most appreciated by the public is likeness, and this usually means expression. It is very doubtful whether the apprentice or improver can have taught to him the art of inducing pleasing and characteristic expression. An important point is a complete mastery of the technical matters of lighting, exposure, and camera manipulations, so that these things are done quite mechanically, and without any mental effort. The mind is thus left free to estimate the sitter's character, to determine the most usual satisfactory expression, and decide on the best means of educing that expression. A good general education and a good address or manner are of first importance, yet they are too frequently quite overlooked when the question of taking up photography as a profession is under consideration. The insight into human nature, which usually comes with such associations as are possible in a public school or a large business, is also valuable. One wants to be able to tell, for instance, how much each man really means when he says he wants no retouching, no flattery. The astute operator will learn more from the man than from his instructions in most cases.

Photographs of the Solar Corona.

It is reported that Dr. Hausky, of the Odessa Observatory, has obtained some photographs of the solar corona, by the aid of certain coloured screens placed in front of the plate, which, if a fact, is interesting, but this must not be accepted unless corroborative proof is obtained at the time of the eclipse next August. It seems at first sight somewhat difficult to understand how the enormous glare of the sun itself can be suppressed by the use of screens, and yet the light from the corona be left intact. The subject
